### Overview

#### 1.1 Main Screen of MARS

After starting MARS, either from the control software or directly, you will see a window with all available test runs (see chapter 2: Manage Test Runs) of the logged in user (chapter 1.2 Login).

After selecting a test run and opening it, the data of the test run will be available in the main window as shown below (this picture was taken from a test run, measured with a CLARIOstar with a build in monochromator and spectrometer):

![Main Screen of MARS](Image)

The window is divided in two areas: The navigation tree on the left side and the working area on the right side. The working area displays your data in different ways, providing several pages which you can access by clicking on the relevant tabs on the top of the working area, e.g. Microplate View (the default page), Table View, Spectrum, Standard Curve, etc. How data is displayed in each page is explained in detail in the chapter 3: Explore Data.

The Ribbon with its task oriented tabs and groups gains you access to all available task.

The status bar at the bottom of the screen shows the reader series used to generate the data and the details of the user logged in with the data path showing where the data is stored. The status icon on the right side of the status bar shows if the application is busy (red) or ready to accept user activities (green).

To check the version numbers of the software and the modules used, click the File tab and then click Info. These version numbers are needed when completing a technical support request.

#### 1.2 Login

##### 1.2.1 Login at Start Up

When starting MARS from the control software screen you do not need to select a login user again. The software automatically starts with the same user as used in the control software. If more than one reader is installed on the computer, or if more than one copy of the software is needed then please read the chapter 1.3: Multiple Installations for more details.

If starting MARS without having the control software running, you will get the same login window as if you had started the control software. Enter the user name and the correct password to log into the desired user.

If a user with the limited rights is used, some of the functions are not available in MARS.

More details about the functions of the login window can be found in the help of the control software or by pressing the F1 key on the keyboard, when the login window is shown.

##### 1.2.2 Changing the User

To change to a new user account in MARS you can either click on the status bar showing the current user or by clicking Change User in the Test Runs group on the Home tab of the Ribbon. Then the login window appears and you can log into the desired user.

#### 1.3 Multiple Installations

It is possible to install the control software part of the reader more than once. For more details on how to do this see chapter 2 of software manual part 1: Installation.

For each installation (called instances) of the control part there is a corresponding instance of MARS. Starting MARS from the control software automatically selects the same instance.

Beside instances you can start MARS more than once even with the same user if you start it directly and not from the control software screen.

#### 1.4 Run MARS in automatic mode

It is possible to run MARS in an automatic mode. This mode can be used to generate automatically character separated value (CSV) text files (see chapter 3.21: Export Data) containing e.g. the result of a calculation (like concentration calculations based on a standards fit).

What happens exactly, when MARS runs in automatic mode?

- MARS watches the test run data base.
- Whenever a new test run was generated with the BMG Labtech control software, this new test run will be opened in background.
- If a template is associated to the protocol of the test run, this template is applied and the defined calculations will be performed (see chapter 5: Using Templates).
- A CSV file based on the table view contents is generated then (the contents of the table view must be defined in the template!).
- The test run will be closed automatically and MARS waits for the next new test run.

MARS can be started in the automatic mode by calling it with the following parameters:

<table>
<thead>
<tr>
<th>First Parameter</th>
<th>Second Parameter</th>
<th>Third Parameter</th>
<th>Fourth Parameter</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reader Short ID</td>
<td>Username</td>
<td>User data directory</td>
<td>3</td>
</tr>
</tbody>
</table>

Note: You can also call MARS only with the parameter -3 to run it in automatic mode. You will be asked for the used reader (if more than one is installed on the computer) and the log-in dialog will be shown to select the user.

**Reader Short ID table:** the Reader Short ID is an ID that identifies the used reader to create the test run:

<table>
<thead>
<tr>
<th>Reader Series</th>
<th>Short ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLARIOstar</td>
<td>CL</td>
</tr>
<tr>
<td>PHERAstar FS, FSX and PHERAstar PLUS</td>
<td>PH</td>
</tr>
<tr>
<td>SPECTROstar Nano</td>
<td>kp</td>
</tr>
<tr>
<td>Omega</td>
<td>OM</td>
</tr>
</tbody>
</table>
Example:
If the reader is a CLARIOstar, the software was installed into the default directory (c:\program files \x86\bmgs), the BMG User is USER and the user data directory is the default directory (c:\program files \x86\bmgs\CLARIOstar\User) then MARS must be called like:
"c:\program files \x86\bmgs\mars\mars" CL USER "c:\program files \x86\bmgs\CLARIOstar\User" -3
You can perform this call manually if you open the Run... menu in the Windows START menu and enter the call like in the example above.

For an automatic starting of MARS you can insert this call in any batch or script tool that allows calling other programs (like windows batch files or BMG LABTECH’s script language).

Note: If MARS was started in automatic mode, no window is opened. You can only see the program item in the notification area of the task bar. If you click on the item the following window opens:

![Application is running in automatic mode.](image)

To close MARS, press the right mouse button over the program item and select the Close menu or click on the item and press the Close Application button.

To see and change the settings for the generated ASCII file, click on the Settings... button to open the file export settings window (see chapter 3.24.3: File Export Settings).

The status line of the AutoMode window shows if a valid connection to the data base succeeded. Click Show Log to see a detailed list of the performed steps and occurred events during the automatic mode.

Click the Change to normal mode... button to stop the automatic mode and start MARS in normal mode.

2 Manage Test runs
The Manage Test Runs window shows you all available test runs of the current user.

You can reach the Manage Test Runs window by clicking Open in the Test Runs group on the Home tab of the Ribbon, or click Open in the File menu.

![Management of files](image)

Note: This window opens automatically when you open MARS or change the user, but not if you select Open Last Test Run in the control software.

Note: The displayed window shows also a menu item above the table for recent test runs and LVIs plates. The LVIs tab is only visible, if test runs measured with the LVIs Micro Drop plate are in the test run data base. To change the displayed table, click on the appropriate menu item.

Select a test run in the table by clicking on it with the mouse. More than one test run can be selected by holding down the Ctrl-Key whilst highlighting the desired test runs with the mouse and clicking on them.

The test run window comes with several possibilities to sort, arrange and filter your test runs. This is explained in detail in the chapter 2.2: Group and Filter Test Runs.

The window provides you the following functions:

- **Open**
  Opens all selected test runs and creates a node for each in the navigation tree

- **Copy**
  Creates a copy of the selected test runs (creating a copy flag indicated by a C in the state column)

- **Delete**
  Deletes all selected test runs.

- **Export**
  Export the selected test runs (for more details see the chapter 2.3: Import / Export Test Runs).

- **Import**
  Import one or more test runs (for more details see the chapter 2.3: Import / Export Test Runs).

- **Merge Test Runs**
  Merge test runs. Learn more about merging test runs in the chapter 2.4: Merging Test Runs

These functions (except the merge functions) are also available on the popup menu of the window. You can open the popup menu by pressing the right mouse button. The popup menu contains three further menu entries:

- **Reset Test Run Settings and Changed Layout**: Select this menu entry to reset the settings and changed layout of the selected test run(s). See chapter 2.5: Test Run Settings and 6.1: Changing Layout.
Assign Layout: Select this menu entry to assign a saved layout to the test run. See chapter 6.2.1: Assign a Saved Layout to a Test Run.

Export Multiple ASCII files...: Select this menu entry to export the selected test runs into ASCII (CSV) files. You will be asked where to save the generated files. Standard file export settings will be used like in the MARS auto mode.

To search a specific test run, you can press CTRL+F Key and enter the text to search. The test run list will then be filtered displaying only these test runs containing the entered text in one of its columns.

If you open a test run created with a quick start protocol the first time, you will see following dialog, to decide, whether to change the well content information of the test run directly or to open the test run normally:

Note: The user can change the order of the columns so they may not appear in the same order as described (see also chapter 2.2: Group and Filter Test Runs).

All tables (microplates, LVIs) contain the following columns:

State
The state field describes the history of a test run. The available states are defined below:

layout changed:
The layout of the test run has been changed after the measurement.

plate IDs changed:
The plate IDs of the test run has been changed after the measurement.

old:
The test run has been imported from an old data base, meaning that no validation checks have been made in its history.

copied:
The test run is a copy of another test run.

merged:
The test run was generated by merging at least two test runs together.

manipulated:
Manipulations have been detected since the generation of the test run (manipulations done outside the evaluation software). Manipulated test runs are shown in read in the test run list.

If the state field is empty, the test run is still in its original state.

Signed
Indicates if the test run is signed ('yes') or not (empty). It is not possible to save further changes to this test run. See chapter 2.5: Test Run Settings.

Test Name
The test name is listed as it is defined in the test protocol.

Date and Time
The date and time that the measurement took place.

Test ID
The unique number of the test run.

2.1 Different Table Views

2.1.1 Microplates Table
In addition to the common columns, the table with the microplate measurements contains the following columns:

ID 1 / ID 2 / ID 3
These are the plate identifiers that were created before the measurement.

Measurement Method
The measured method (e.g. absorbance, fluorescence...)

# Wells
The plate format (number of wells) of the microplate.

Protocol Comment
The comment of the test run protocol entered with the control software.

Plate
The name of the used microplate.

2.1.2 BMG LVIs Micro Drop plates Table
The BMG LVIs Micro Drop plates table shows the same columns as the Microplate table without the #Wells and the Plate column.

2.2 Group and Filter Test Runs
The test run's table provides powerful functions to help order the stored test runs. The user can sort, group, use filtering and change the order of columns to help find data and to achieve their most useful view of the test run list.

If you change the settings of the test run table to your needs, MARS memorizes the settings when you close the software and will restore them when you open it again.

2.2.1 Sorting the Table
The table can be easily sorted by clicking on the column you want to sort by. By clicking once on a column header the list will be sorted in that column. This is indicated by a little arrow in the column header. Clicking on the column header a second time, will sort the list in a descending order by that column.

It is possible to create a hierarchic sorting list, using more than one column. Just select the main column in the list to sort by and sort it as described above. To select the second sorting parameter press and hold the Shift-Key on the keyboard, click on the second column header you want as a next sort key and so on with each new sort key.
2.2.2 Grouping the Table

In the window above you see a grouped table. The grouping column is the Measurement Method column. As you see, the table contains blocks for each Measurement Method in the list. You can expand or close each block by clicking on the + or - button before each block header.

Grouping helps in ordering your test runs and makes finding a specific test run easy.

How to Group the List

The list can be grouped using the mouse. Move the mouse cursor to the header of the column you want to use as a group criterion. Click the left mouse button and keep it pressed, then move the mouse cursor and highlighted column header to the gray area above the list releasing the left mouse button when the cursor is over the area, the data will then be sorted by the data in that column.

As with the hierarchic sorting you can also group hierarchically by selecting another column to drag to the group area.

2.2.3 Change the Position of a Column

If the default order of the columns is not suitable, you can change the position of each column manually. Click on the column header you want to move, and keep the mouse button down whilst dragging the column to the new position. When a position is reached where you drop the column two green arrows are displayed, the column can then be dropped into one of these positions.

2.2.4 Filtering the Table

You can filter your list by nearly any filter criterion. The easiest way of defining a filter is to click on the small down arrow of the column header which appears if you move the mouse cursor over the header. A list with the whole content of the column will then be displayed:

When a filter is defined, this is indicated by a new line which appears at the top of the list:

There the filter can be deleted by clicking the red button with the cross (×). If you want to discard the filter temporarily but leave the definition for later use, just deselect the check-box before the filter description by clicking on it, and to restore the filter again just click again in the check box.

It is possible to further customize the filter. Press the Custom list entry in the drop down menu to open the customize window. Try out this function to learn how powerful this is.

Searching in the Table

To locate information within the table, you can use the search function. Press the magnifier button at the top right corner or CTRL+F to open the search entry field at the bottom of the table. Enter the text to search and press **Find**. The list will filter records, displaying only those that contain the entered search string (the search is case-insensitive).

Extended Search Syntax

The following specifiers and wildcards can be used to narrow search results:

The "*" specifier. Preceding a condition with this specifier causes the table to display only records that match this condition. The "+" specifier implements the logical AND operator. There should be no space character between the "*" sign and the condition.

The "~" specifier. Preceding a condition with "~" excludes records that match this condition from search results. There should be no space between the "~" sign and the condition.

The percent ("%") wildcard. This wildcard substitutes any number of characters in a condition.

The underscore ("_") wildcard. This wildcard represents any single character in a condition.

For instance, applying the 'fluorescence TRF +9902 +EV =lin -copied' search string makes the grid display only records that include 'fluorescence ' or 'TRF ' with '9902' and 'EV ' in any cell, and do not include either 'lin' or 'copied'.

2.3 Import / Export Test Runs

2.3.1 Import Test Runs

Using the import function you can import test runs. Click on the **Import** button in the menu on the manage test runs window and a standard file window opens where you can select a file with the test runs you want to import into the current users data. Imported test runs will be added to the test run list and marked.
Note: It is allowed to import test runs, generated with different reader families. Because of technical reasons, not all test runs are compatible.

Note: Test runs generated with a newer version of the same reader family software cannot be imported if database format has changed.

If you have installed the newer BMG control software you can also use drag and drop to import test run files (*.ruc). Select the file with the test run in the Windows Explorer, hold down the left mouse button and move the mouse over the manage test runs window. Leave the mouse button and the test run(s) in the *.ruc file will be imported.

2.3.2 Export Test Runs

You can export one or more test runs as one file to exchange it between users.

Note: If making a support request regarding the test run(s) it is useful to include exported data that demonstrates the problems experienced as this can help in finding and solving the problem.

If the manage test runs window is open, just select the test run(s) you want to export in the list and click on the Export button in the menu on the top of the window.

If you want to export only the currently opened and active test run (the one which is selected in the navigation tree), click Export in the Test Runs group on the Home tab of the Ribbon or click the Export item in the File menu:

A standard file window will appear where a file destination can be selected to save the exported test runs. Define a name for the file (or accept the proposed one) and press the Save button. The extension of the file name will be added automatically and is always .RUC. Please do not change the extension manually as this will mean that the created file will not be recognized by the software when trying to re-import the file.

2.4 Merging Test Runs

2.4.1 What Means Merging Test Runs

The merging test runs function can be used to add the data of one test run to another test run, resulting in a new test run containing the data of both. There are three ways to merge test runs together:

- The kinetic cycles/ intervals of two test runs can be merged so that the new number of cycles/ intervals is the sum of the number of cycles/intervals of each.
- The wavelengths of two or more test runs can also be merged so that the number of wavelengths in the merged test run is the sum of the number of wavelengths of each.
- The wells of two test runs if each well is measured in only one of the test runs can be merged to a new test runs containing the union of all wells.

To merge two or more test runs together highlight the test runs in the test run table in the manage test runs window. The merge buttons in the toolbar will be enabled if the selected test runs pass checks to establish if the data can be merged.

After you’ve selected two or more test runs to merge and selected the merge mode, a dialog opens which allows you to decide whether to keep the original test runs or not:

If the radio box control Keep original test runs is selected, the test runs will be merged into a new test run, if Merge into original test runs is selected, the test runs will be merged into the first of your selected ones and deleted after the merge is completed.

The data checks needed for merging test runs using either cycles or wavelengths are explained in the following two sections.

Note: Possible saved settings (including changed layouts) of the test runs to be merged will be lost!

2.4.2 Merge Cycles / Intervals

To merge two test runs by cycles/ intervals press the Merge Cycles button in the Merge Test Runs menu on the manage test runs menu.

The following conditions must be fulfilled to merge two test runs by cycles/ intervals:

- The number of wavelengths used must be identical or - if the measurement is a spectrum - the measured spectra must be identical (start-, stop wavelength and resolution).
- The sum of the resulting cycles/ intervals must be less than 6000 (for the SPECTROstar Nano, the limitation of the data base is 1000).
- The measurement method must be identical
- The layout must be identical
- The measurement mode must be identical (fast kinetic [well mode] or slow kinetic [plate mode])
- The test runs must not contain well scanning data

The cycle/ interval times for the merged test runs of kinetic data are calculated as follows:

\[ t = (\text{time of last cycle/interval}) + (\text{Start time of second test run}) - (\text{Start time of first test run}). \]

2.4.3 Merge Wavelength

To merge the wavelengths of two test runs press the Merge Wavelength button in the Merge Test Runs menu on the manage test runs menu.

The following conditions must be fulfilled to merge two test runs by wavelength:

- The number of cycles/ intervals must be identical
- The layout must be identical
- The measurement mode must be identical (fast kinetic [well mode] or slow kinetic [plate mode])
- The test runs must not contain spectrum data
- The measurement method should be identical - but it is not a requirement

Note: If test runs performed using different measurement methods are merged, the merged test run gains the settings of the first of the two test runs. For example, if
you merge an absorbance test run with a fluorescence intensity test run, the merged test run data would be represented as an absorbance run - even though the fluorescence data covers a completely different range.

2.4.4 Merge Wells
To merge the wells of two microplate measurements to a new microplate, press the Merge Wells button in the Merge Test Runs menu on the manage test runs menu.

The following conditions must be fulfilled to merge the wells of two test runs:
- The number of wavelengths used must be identical
- The number of cycles/Intervals must be identical.
- The measurement method must be identical
- The layout must be disjunctive. That means measured wells in on test run are not allowed in the other test run.
- If the test runs contain spectra, the measured spectra must be identical (start-, stop wavelength and resolution).

2.5 Test Run Settings
Each test run comes with its own list of settings. These settings store most of the display parameters and the performed calculations for that test run as well as settings for print and excel reports. When you open a test run for the first time default settings will be assigned to the test run. Checks are performed and the default settings are determined using the first condition that matches the defined criteria as below:

- If the test run has already its own setting file, it will be used (e.g. from earlier opening the test run).
- If the test protocol which created the test run has a template (see chapter 5: Using Templates), the setting will be generated according to that template.
- If there is a default template for the type of measurement method (see chapter 5: Using Templates) the setting will be generated according to that template.
- If none of the above conditions are met, a new standard setting file will be generated.

Important settings for a test run could be to show:

- All performed calculations (like blank correction, replicate statistics, standard calculations...). If the test run contains a measured spectrum all manually defined wavelengths are stored in the setting file.
- Defined Variables (see chapter 4.2.1: Define and Use Variables)
- The selected nodes in the navigation tree and the content filter tree (see chapter 3.1: Navigation Tree and 3.2: Content Filter Tree to read more details about selecting nodes to display data).
- The displayed View (Microplate View / Table View / Signal Curve / Spectrum Curve ...) and the special settings of the view.
- The defined print report layout and pages
- A changed microplate layout
- The defined excel report settings and pages

If you change settings of a test run and you close the test run, you will be asked if you want to save these settings. If you confirm these settings, you will be able to continue your work after reopening the test run at the same point as you closed it.

If you changed the layout of a test run (see chapter 6.1: Changing Layout) the changed layout will also be saved then.

Note: Run Only users cannot save the changed settings and even cannot change the layout of a test run.

To remove all performed settings (even an assigned template) of an opened test run, select in the quick access toolbar. The test run settings will be deleted and the format will be reconfigured to default settings using rule 3 of the list above.

To reset settings without applying default settings use the clear button ( ) in the quick access toolbar.

Resetting settings of a test run does not reset a changed layout. To reset both, settings and the layout, select the menu entry Reset Layout in the Test Run Layout group on the Layout tab of the Ribbon.

In addition you can reset settings and changed layouts of closed test runs, if you select the menu entry Reset Test Run Settings and Changed Layout on the popup menu of the Manage Test Runs window after you've selected the test runs in the list.

If you export or import a test run, the settings (including a changed layout) will be exported / imported as well.

After a test run has been signed (see chapter 7: Sign a Test Run) no further changes can be made to the settings. You can open the test run and change settings online, but they will not be saved or exported.

3 Explore Data
After opening one or more test runs you can explore the data using the commands on the different ribbon tabs, the Quick Access Toolbar and the File menu:

The Ribbon with its tabs, the Quick Access Toolbar and the commands in the File Menu gains you access to the complete functionality of the software. All of the available data (raw data and created data) are listed in the navigation tree on the left side of the screen. After selecting one or more data nodes in the navigation tree, you will see the data in the working area.

Use the Maximize and Restore button on the top right area of the working area to maximize the displayed working area or to restore a maximized working area to the normal size. If the working area is maximized, the navigation tree will be collapsed and the test run information on top of the page disappears. The navigation tree can be manually reopened again.

There can be up to eight different pages in the working area where data can be inspected using different formats. Data can be obtained using the following tabs:

If the data has well scanning data and areas inside the well where defined, the tap will appear after the Table View tab.
If the data has a measured spectrum (readers with an installed monochromator or spectrometer) the tab ![Spectrum](#) will also appear. A notifications tab ([Measurement notifications](#)) appears, if one or more warnings occurred during the measurement of the test run.

If the data comes from a BMG LVis Micro Drop plate, ![Microplate View](#) tab is replace by the ![LVis Plate View](#).

To change the visible page click on the tab of the page you want to open. Only pages with visible data will have a tab, e.g. the tab for the Standard Curve will only appear when a standard calculation has been performed.

Each page is explained in detail on the according help page:

**Microplate View / LVIs Plate View**
Data is displayed in a grid according to the microplate format. For BMG LVis Micro Drop measurements, the grid has two columns and eight rows.

**Table View**
Data is displayed in an Excel-like table format.

**Area Statistics**
Displays statistic data of defined areas inside wells of a well scanning test run.

**Spectrum Curve**
Displays a chart with the spectral curve(s) of the selected well(s)

**Signal Curve**
Displays a chart with the kinetic data of the selected well(s)

**Standard Curve**
The standards data are shown plotted in graphs with fitted curve(s).

**Enzyme Kinetic Fit(s)**
The results (e.g. saturation curve) of enzyme kinetic calculations are shown plotted in graphs with fitted curve(s) (Michaelis-Menten, Lineweaver-Burk, ...)

**Binding Kinetics**
The results of a kinetic rate equation are shown plotted in a graph.

**Protocol Information**
Displays the settings used in the test run protocol.

**21 CFR part 11**
Displays information relevant to fulfill the FDA 21 CFR part 11 compliance, including a full audit trail and signatures (if a test run is signed)

**Measurement notifications**
Only available if warnings or notifications occurred during the measurement. Displays a list with all occurred warnings and notifications.

3.1 Navigation Tree

The navigation tree is the main tool used to select the data displayed in the working area (see chapter 3: Explore Your Data). It contains two sections.

The upper section displays the tree with all opened test runs and sub nodes. Each test run has further sub nodes showing all available data (measured or calculated). If more than one test run is opened, the last opened test run is always shown at the top of the tree. Read more about this tree in the section 3.1.1: Using the Tree.

The border can be changed to alter the partitioning of the sections (drag using the mouse to its new position).

The lower section contains two parts, the first containing a detail window, which displays detailed information about the selected node in the tree above (the selected node is indicated by a bold caption and a surrounding dotted border).

The second part shows a further selection tree, called a content filter tree. The data shown here is dependent upon the selected page in the working area.

### 3.1.1 Using the Tree

A tree is a hierarchical structure with a set of linked nodes. Each node in the tree has zero or more sub nodes. If there are no sub nodes it represents data that can be displayed in the working area. The top node in the tree represents an opened test run.

Each opened test run is represented by its own tree. The number of nodes and the kind of data the end nodes represent depends on the kind of test run (Layout, measurement mode...) and the calculations defined by the user or a template (see chapter 5: Using Templates).
Common Functions
You can expand or close each node in a tree that contains sub nodes by clicking on the button ( ) for expand, ( ) for close) before the node. If you select the tree of a different test run, then this test run becomes the current test run and will be expanded automatically. The tree of the previous current test run will be closed (but not removed).

The header of the navigation area has a little pin on the right border. You can use this pin to change between auto hide or fix to the area by clicking on the pin:

If the pin is fixed ( ) then the area is fixed and can only change in width by dragging the separating border using the mouse between the navigation tree and the working area.

Note: There is a maximum size of the navigation area when fixed. The size depends on the size of the working area, the size of the main window and the resolution of your screen.

If the pin is unfixed (like in the image on the left) the area will automatically be closed if you move the mouse out of this area. Moving the mouse to the little navigation tab on the left side of the application window (this is only displayed when the pin is not fixed), the navigation tree will appear again.

In auto hide mode, there is more room left for the working area as the tree will be displayed above the working area if it appears

The whole navigation tree can also be dragged by clicking on its header whilst holding the left mouse button down to move it away from its position. The navigation tree will then become a separate window that can be moved and sized in any direction. It is possible to close the window from here. To reopen it again press Ctrl+N or click Show Navigation Tree in the Navigation group on the View tab of the Ribbon.

Selecting Nodes
To display your data in the working area you have to select the corresponding node in the navigation tree and - if you display a chart (like the signal curve view, the standard curve view, the enzyme kinetic fit(s) view or the spectrum curve view) also the content in the content filter tree. Depending on the active page in the working area, the navigation tree can have two different modes to select nodes.

Selecting data for microplate or table view
If the microplate view or the table view is active, the navigation tree has a column, called Row. Behind each selectable end node, the column Row contains a little box. If a node is selected, its box is colored.

Each color of the selected nodes represents a data row in the microplate view or a data column in the table view:

To select a node in this mode

- click with the mouse into the box behind the node you want to select or
- use the menu item Select/Deselected Node either in the Navigation group on the View tab or in the popup menu of the tree.

A selected node will now be deselected (the box is white then) and a deselected box will be selected by using the next free available color. That means, if you have already used the color green and blue for other nodes, the red color will be used for this node. If no colors are left, the node will not be selected. You can select one row and deselect all selected nodes at once. Therefor you have to click on the row you want to select (it must be an unselected row) and select the Select row (Deselect all others) menu item in the pop up menu (opened with a click on the right mouse button). If you want to deselect all nodes (without selecting a new row), click on a selected node, open the pop up menu and select the menu item Deselect all rows. You can change the number of selectable rows up to 10. How to do this, you can read in the section MARS Settings / Navigation Tree Settings

Changing the position of displayed rows
In the microplate view or the table view you can change the row or column positions of the displayed data with the mouse. You can do this either in the displayed legend below the tables by clicking on the according data entry in the legend and move the entry to the new position (in the legend). Alternatively you can select the row you want to move in the microplate view by clicking on one of the according color in the first column of the microplate table and moving it to the new position. In the table view you can move the column by clicking on its header and moving it to the new position (see chapter 2.2.3: Change the Position of a Column).

Selecting data for curve charts
If a chart is active such as the signal curve view, spectrum curve view, standard curve view or enzyme kinetic fit curve, the column Row in the tree will vanish and a small check box will
appear before each selectable node. The data you wish to be displayed can be selected or deselected by clicking on the check boxes of the available nodes.

Note: Only nodes that can be selected for the active chart have a check box, e.g. if a test run has kinetic data and the signal curve view is active, only nodes with kinetic data will have a check box.

**Tree Popup Menu**

If you move the mouse in the navigation tree area and press the right mouse button, a popup menu opens which gives access to important functions linked to test runs and tree nodes:

1. Closes the current test run
2. Exports the current test run (see chapter 2.3.2: Export Test Runs)
3. Selects or deselects a node (if selectable). Alternatively you can double click on the node.
4. Deselects all selected nodes at once (if opened on a selected node)/
   Select node and deselect all other rows (if opened on a not selected node)
5. Change the displayed name/title of the node (only available for nodes referring to performed calculations)
6. Deletes the node (if not the basis of a calculation)
7. Opens a window to change the number format setting of the selected data.
8. Opens a window to change calculation parameters (only available for calculation nodes).
9. Creates a template with the current settings of the current test run.
10. Assigns a template to the current test run and overwrites its settings.
11. Signs the current test run
12. Saves the test run settings.
13. Resets the settings of the test run to the default values
14. Removes all settings of the test run.
15. Highlights the Result Node in the display area (Microplate View, Table View)

All the functions are also available in the Ribbon.

**Note:** The popup menu shows only these functions which are independent from the selected node or applicable on the selected node.

**Change the caption of a generated node**

The captions of the nodes in the tree are generated by the program. If the node represents data or the result of a calculation, you can change the caption of the node.

Therefore you need to select the node in the tree and open the tree popup menu by pressing the right mouse button. Select Change Node Caption in the menu and the representation of the node changes into edit mode:

Now you can enter a new caption. If an empty caption was entered, the text <empty> will be used automatically as an empty value is not allowed.

You can change at any time back to the original node caption. Therefore you have to select the node again, open the popup menu and select Restore Original Node Caption.

**Note:** If you change the caption of a node in a dual channel or multiple chromatic measurement, all nodes representing data of the same channel/chromatic in all following nodes will be changed as well.

**Summary of all Possible Nodes**

Each test run consists of static nodes which are generated when a test run is opened. These are the nodes for the test settings and the nodes for the raw data. They cannot be removed. The test setting nodes represents data that was defined in the control software.

Default templates perform some calculations like blank corrections and replicate statistics. The other nodes are created either by the user manually or by using a template. See chapter 5: Using Templates.

**Test run name:**

Top most nodes. Represents the test run. The displayed icon depends on the type of test run (microplate, LVis plate). The name is the name of the test run followed by its internal test run id. If Detailed Captions is selected (View group on the ribbon, section Navigation), the plate IDs of the test run are also part of the name.

**Test Settings**

Parent node for all test settings sub nodes

**Layout**

Select this node to display the layout in the microplate view

**Group IDs**

Represents defined group IDs. See chapter 6.1: Changing Layout.

**Standard Concentrations**

Represents the concentration values of the standards or controls (appears only if standards where defined in the layout or controls with a standard concentration was defined. See chapter 6.1.3: Changing Concentrations, Dilutions and Sample IDs).

**Dilutions**

Represents the dilution factor for the wells (appears only if dilution factor > 1 was defined).

**Sample IDs**

Represents the sample IDs of the samples (appears only if sample IDs where defined for the samples)

**Injections**

Parent node for all injection volume nodes (appears only if there have been injections in the test run)

**Volume n**

Sub nodes of Injections, for each defined injection volume (n is the number of the volume)
Data
Parent node for the raw data and the corrected raw data

Temperature
Represents the temperature during the test run measurement.
(Appears only if temperature monitoring or incubation was set in the control software)

Raw Data
Represents the raw data. If the test run has only one measured wavelength, the used Filter(s)/Wavelength is displayed in brackets behind the node name. If the test run is a well scan test run, a short description of the used calculation method to get the raw data value from the scan point values in the well (average, sum, median...) is displayed in brackets behind the node name.

Wavelength: lambda/filter
Always end node and possible sub node of each data node (raw data or calculated data). Appears if the test run contains more than one measured wavelength, or if it is a spectrum test run and you added a wavelength to the test run (see chapter 3.12.1: Adding, Changing or Removing Wavelengths). The used filter(s) or the added lambda value of the wavelength is also part of the nodes name. If the test run was measured with the PHERAstar series, the number of the used optic module is displayed in brackets after the wavelength information.

Parallel
Only for fluorescence polarization measurements. Represents the parallel measurement channel

Perpendicular
Only for fluorescence polarization measurements. Represents the perpendicular measurement channel

Spectrum
Appears only for test runs with a measured spectrum. Represents the spectrum curves.

Spectrum calculations (Sum, Maximum, Minimum, Local maxima, Local minima, inflection points, Average, Slope, Maximum of slope)
Represents the calculated data taken from a spectrum range. The range used for the calculation is displayed behind the calculation method (e.g. Sum of Range 1). See chapter 4.18: Spectrum Calculations. Performed calculations of the types Local maxima, Local minima and inflection points can have more than one sub nodes, for each calculated minima, maxima or inflection point.

Blank corrected
Represents the blank corrected raw data (if the layout contains blanks)

Blank corrected (all groups) / Neg. control correction /Neg. control correction (all groups)
Represents the data of performed corrections (see chapter 4.4: Corrections).

FP calculations (Polarization, Anisotropy, Intensity)
Represents the calculations available for fluorescence polarization measurements (see chapter 4.6.1: FP Calculations).

TR FRET Calculations (Ratio, DeltaF)
Represents the ratio and the DeltaF calculation for time resolved fluorescence (dual emission) test runs (see chapter 4.6.2: TR-FRET Calculations).

Statistics
Well statistics (Average, Standard deviation, Standard deviation n, % CV, % CV n, Minimum, Maximum, Median, Sum, No. of Values)
Represents the calculated statistical data for replicates (see chapter 4.5: Statistics), layout groups or for selected wells (see chapter 4.19: Statistic over Wells).

Curve Smoothing
Represents the smoothed signal curve for a defined range, using the moving average method. The moving width of the method is b. The number of the used range is n. See chapter 4.7: Curve Smoothing.

Kinetic fit calculations (Linear regression fit, Logarithmic fit, Exponential fit, Double logarithmic fit, 4-Parameter fit, Segmental regression fit, 2nd Polynomial fit, 3rd Polynomial fit, Hyperbola fit, of Range n)
Represents a curve fit calculation based on the range n of the signal curve. See chapter 4.9: Kinetic Fit Calculations.

Kinetic fit result parameters (parameter of fit method (Range n))
Represents the parameter calculation of a curve fit calculation based on the range n of the signal curve. The calculated parameter and the used fit method are part of the node name. See chapter 4.9: Kinetic Fit Calculations.

Kinetic calculations (Slope, Time to threshold, Time to max, Sum, Average, Maximum, Minimum, Standard deviation, Standard deviation n, % CV, % CV n, Maximum of slope, Time to max slope, Median)
Represents the calculated data taken from a kinetic range. The range used for the calculation is displayed behind the calculation method (e.g. Slope of Range 1). See chapter 4.8: Kinetic Calculations.

Standards calculations (Linear regression fit, 4-Parameter fit, Cubic spline fit, Point to point fit, Segmental regression fit, 2nd polynomial fit, 3rd polynomial fit, Hyperbola fit)
Represents the recalculated concentrations taken from the standard curve fit results (see chapter 4.10: Standard Calculation / Curve Fitting).

Concentration calculations (Difference, Ratio known/calc, Ratio calc/know, Percentage deviation)
Represents the result of performed calculations based on known and recalculated concentrations (only available if a standard fit was performed). See chapter 4.11: Concentration Calculations.

Calculations (data 1 / data 2, data 1 - data 2, data 1 + data 2)
Represents the results of performed calculations as displayed (*, /, +, or -). Data 1 and data 2 will be replaced by the input data selected for the calculation (see chapter 4.12: Data Calculations).

Validations (good / bad, good / bad / unknown)
Represents the result of a performed validation (see chapter 4.13: Validations).

Assay Quality (Z' based on Cnt1 and Cnt2, Signal to blank (Cnt), Signal to noise (Cnt), Percentage calculation)
Represents the result of a performed assay quality calculation (Z’, signal to blank, signal to noise and percentage calculation). Cnt, Cnt1 and Cnt2 will be replaced by the selected content on which the calculation is based on (for Signal to blank Cnt is the used blank, for Signal to noise, Cnt is the used noise see chapter 4.14: Assay Quality)
**User Defined Formula (entered formula name)**
Represents the result of a performed calculation based on an entered well based formula (see chapter 4.15: User Defined Formula)

**Enzyme Kinetic** (Michaelis-Menten fit, Lineweaver-Burk fit, Eadie-Hofstee fit, Scatchard fit, Hanes-Woolf fit)
Represents the result of a performed enzyme kinetic calculation (see chapter 4.16: Enzyme Kinetic Calculation).

**% Curve Scaling (scaled curve (Range n))**
Represents the result of a performed curve scaling calculation (see chapter 4.17: Curve Scaling).

**Binding Kinetics (kinetic rate equation)**
Represents the result of a performed kinetic rate equation (see chapter 4.25: Binding Kinetics Calculation).

**Curve Analysis (Area under Curve, Differentiation, Integration)**
Represents the result of a performed curve analysis equation (see chapter 4.24: Curve Analysis).

### 3.1.2 Detailed Information on the Selected Node

The detail window is shown under the navigation tree, if neither the signal curve view nor the spectrum curve view is active. In this case, the area contains the content filter tree.

The detail window displays detailed information to a selected node in the navigation tree (if available). The type of data displayed depends on the represented data of the selected node.

For each performed calculation, it contains the work flow for that calculation from the last input data down to the first input data which leads to the result.

In case of the linear fit in the screen shot shown below, the linear fit was performed on a kinetic calculation (sum) of range 1. The kinetic calculation was performed based on blank corrected data, which again are based on the raw data.

Following the work flow are the parameters of the calculation. In addition to the standard curve fit data, it also displays the performed fit formula and the result fit parameter.

### 3.2 Content Filter Tree

The content filter tree is part of the navigation area containing the navigation tree. Read more about trees in the section 3.1.1: Using the Tree.

The content filter tree replaces the area where the detailed window is shown if you change to either the signal curve page (for kinetic test runs) or the spectrum curve page (for absorbance spectrum test runs only) in the working area.

The navigation tree is used to select the data you want to view (i.e. blank corrected raw data). The content filter tree lets you select the wells you want to display in the graph of the working area.

If you’ve already selected wells in the microplate view, the LVIs view these wells are also selected in the content filter tree when it appears.

In addition the content filter tree allows you to select groups of wells, for example replicates or a series of wells that have received the same treatment. The tree is organized hierarchically with the end nodes representing the wells. The parent nodes of the end nodes represent the replicates of wells (only applicable where replicates were defined in the layout). The next level groups all elements of the same content type (i.e. all samples or all standards). The highest level (top most nodes) represent the groups (Only if groups are defined), otherwise the root node is visible, representing all wells.

Clicking on the check box shown before the node representing a well or group of wells will select them for use. The highlighted well (well 803 in the screen shot above) in the content tree corresponds to the selected curve in either the signal curve or the spectrum curve charts. Changing the selected curve in the chart will also highlight the corresponding well in the tree, and will expand the parent nodes.

If the tree is too large to fit in the area, a scroll bar is displayed on the right side of the tree to change the visible part of the tree. The size of the visible area for the content filter tree can also be increased by moving the splitter above the tree upwards.

### 3.3 Microplate View

The initial page on the working area for measured microplates is the Microplate View page.

**Note:** If the open test run is a BMG LVIs Micro Drop measurement, the title changes to LVIs Plate View.

In this view, data is displayed according to the defined microplate layout. The navigation tree can be used to select the data you want to see.
The upper section of the page displays detailed information of the test run: the name of the test run, the measurement date and time, the defined test run ID’s (ID1-ID3), the measurement mode and if the test run is signed or manipulated.

At the bottom of the page you see the legend for the displayed data.

With the excel button ( ), you can export the displayed data to excel (see chapter 3.21: Export Data) (you need to have installed a Microsoft Excel version 97 or higher on your PC).

With the ASCII Export button ( ), you can export the displayed data into a text file. The data are stored in the comma separated value (CSV) format (see chapter 3.21: Export Data).

With the change layout button ( ) above the microplate table, you can directly open the window to change the test runs layout (see chapter 6: Change Test Run Layout).

Popup Window

The Microplate View page has a popup menu that can be reached by pressing the right mouse button in the main window:

- Don’t use the selected well(s) (see Exclude Wells)
- Reuse excluded wells (see Exclude Wells)
- Perform a statistic over the selected wells (see Statistic over Wells)
- Open the Outlier Detection dialog (see Outlier Detection)
- Copy the Microplate View as text to the clipboard.
- Copy the Microplate View as a graphic to the clipboard.
- Export data to Excel...
- Create Bar Chart from selected wells...
- Create Microplate Bar Chart...

Display legend in first column

Check this button to display the legend in the first column of the grid, for each row:

This is useful for non-colored printing reports, to see the description of the data according to the row in the Microplate View.

3.3.1 View Modes

The Microplate View page can display the data in up to five different modes. You can change the mode with the view mode buttons found above the microplate grid.

Depending on the test runs’ measurement method there can be up to four modes available for a test run.

If groups are defined in the layout, the background of a microplate grid well will be drawn in a unique color for each group.

Value mode

Displays the values of the selected data nodes that can be expressed in one number. If the test-run is a kinetic (having cycles or intervals), the value for a selected cycle/interval can be displayed in each well (see section Kinetic Test Runs). The screenshot at the top of this page shows the Microplate View in value mode.

If concentration values are displayed in the grid and a unit is defined for concentrations, you can display the unit behind the value if you check the Show Units control above the grid.

Color mode

Displays the values in different color modes: Good/Bad decision (one color for all values above a threshold, one color for the other values), Three colors (two limits defining the borders for the three colors) or Color gradient, which displays the values in different shades of colors between a defined range. You can enter and change the settings for the color view mode in the color settings window. To open the window, press the color button ( ) behind the color mode check box. To adjust the color settings, you can use the color range selector on the right side of the microplate view. This screenshot is an example for data displayed in Color gradient mode:

Kinetic mode

This mode is only available for kinetic test runs. It displays kinetic curves in the wells used for each selected data node that can be applied to the kinetic data (i.e. Blank corrected values or multiple wavelengths will show as multiple curves in each well):

The scaling for the horizontal and vertical axis depends on the scale settings. Default vertical scaling is the minimum and maximum values of all displayed curves. The default horizontal (time) scaling starts from the first cycle to the last one. The scaling can be changed in the Curve Scaling Settings dialog which can be opened with the settings button ( ) on the right side of the Kinetic Curves check box.

If kinetic ranges are defined (see chapter 4.1 Ranges) and only the Kinetic Mode is selected, you can select whether you want to...
see all kinetic cycles/intervals or if you want to see only a cut-out of the kinetic defined by one or more ranges with the drop down list on the right side above the table.

The curves color is defined by the selected row in the navigation tree. For better contrast you can define to print all curves in black. This can be defined in the MARS options dialog.

### Spectrum mode

This mode is only available for measured spectra. It displays the spectrum curve of the selected spectrum node for each well. On the bottom of each well, a small spectrum bar is displayed that gives you an overview of the measured spectrum. You can hide this bar using the Spectrum Display Settings window. If the measurement has a kinetic, you can select the cycle with the drop down list for cycles on the top right side of the grid, or you can display the spectra of each cycle at once (overlapping) if you check the All Cycles control above the grid.

The scaling for the horizontal and vertical axis depends on the scale settings. Default vertical scaling is the minimum and maximum values of all displayed curves. The default horizontal (wavelength) scaling starts from the first wavelength to the last one. The scaling can be changed in the Curve Scaling Settings dialog which can be opened with the settings button () on the right side of the Spectrum Curves check box.

### Well scan mode

This mode is only available if your test run contains well scanning data. It displays each scanned point in the well in a color, defined with the color settings window. The data can be displayed in the same three modes like in the color mode. Only raw data can be displayed using this mode. Meaning that the selected nodes in the navigation tree have no influence on the displayed data in this mode.

If your measurement contains more than one measured wavelength (dual channel or multiple wavelength test run), you can select the wavelength you want to display, with the drop down list on the top of the microplate grid (only visible in this mode). Read more about well scanning in the chapter 3.22: Well Scanning Data.

The available view modes can be combined if you select more than one of the check box controls. If you combine the view modes, you will see all selected view modes side by side in each grid cell. If you combine the Color mode with the Value mode, the value will be shown above the color (the color is used as a background color for the value mode).

### Kinetic Test Runs

You can display an overview of the kinetic curves for each well with the Kinetic View Mode (see chapter 3.3.1: View Modes). In the Value View Mode, and in the Color View Mode, you can select the cycle/interval you want to inspect using the kinetic drop down list at the top right of the microplate grid:

- Select the ‘All cycles/Intervals’ check box and in Color Mode color bar representing each cycle/interval will be shown in each well.

### Absorbance Data

Absorbance measurement data and curves can be shown as OD values, as milliOD values (mOD) or as transmission values (in % Transmission). An additional button appears in the Display group on the Home tab of the Ribbon when an absorbance test run is open allowing the user to select the most appropriate mode for the data to be expressed.

You can also find a command button for each of the three modes in the Working Area group on the View tab.

### Scale Settings for Kinetic and Spectrum Curves

The settings for the horizontal and vertical axis scaling of the displayed curves in the microplate view can be adjusted. Select the settings button () for either the kinetic curves or the spectrum curves to open the Curve Scaling Settings dialog:

**Horizontal Axis Scaling:** select a range (kinetic or wavelength) to define the scale (if there is no range with the desired scale, you can create a new range using the Ranges button).

**Vertical Axis Scaling:** You can choose between three settings:

- automatic scaling over all selected data (minimum and maximum is calculated from all selected data over all wells)
- automatic scaling individual for each selected data (minimum and maximum is calculated separately for each selected data but over all wells)
- fix scaling (enter the desired minimum and maximum value for the axis scaling).

### 3.3.2 Selecting Wells

You can select one or more wells in the Microplate View using the mouse. To select one well, just click on it with the left mouse button. To select an area of adjacent wells, press the left mouse button over the first well you want to select, and keep it pressed...
dragging the mouse cursor over to the last well of the area before releasing the mouse button.

To select a collection of wells allotted over the microplate grid, press the Ctrl-Key on your keyboard and click with the left mouse button on each well you want to select.

To select a whole row or a column on the grid, click on the appropriate row letter or column number. The selected wells are indicated by a black border around the well.

A double click on a well performs an action that depends on the preset viewing mode:

<table>
<thead>
<tr>
<th>View Mode</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Value mode</td>
<td>Opens a windows with detail information of the well (see chapter 3.3.3: Details of a Well below)</td>
</tr>
<tr>
<td>Color mode</td>
<td>Changes to the signal curve view page and displays the selected well(s) in the chart.</td>
</tr>
<tr>
<td>Kinetic curve mode</td>
<td>Changes to the spectrum curve view page and displays the selected well(s) in the chart.</td>
</tr>
<tr>
<td>Spectrum curve mode</td>
<td>Changes to the spectrum curve view page and displays the selected well(s) in the chart.</td>
</tr>
<tr>
<td>Well scan mode</td>
<td>Opens a window with a detailed view on the well scanning values of the well (see chapter 3.22: Well Scanning Data)</td>
</tr>
</tbody>
</table>

The selection of one or more wells also leads to a selection of the associated nodes in the content filter tree.

3.3.3 Details of a Well
The window, Details of Well <WellName> appears after double clicking on a well in the Microplate View, if the Value Mode or Color Mode is in use. Alternatively you can click Well Details in the Working Area group on the View tab of the Ribbon, which will also work if the other view modes are in use.

Note: If more than one well is selected, the details of the first selected well will be displayed.

The detail window shows layout information of the well and content such as, associated group, sample ID and concentrations (if available). If the test run includes injections, then the volumes used and the injection time values are also displayed in a table for each well.

The bottom part of the window displays the values of the selected nodes in the navigation tree for that well.

Note: If the test run was created with a NEPHELOStar reader, the injection information Start time (plate mode tests only) and Duration are not available.

3.3.4 Zooming
If there are many data values shown in one well or if using a microplate format with 384, 1536 or 3456 wells, the values in one well can appear very small and become difficult to read. To overcome this it is possible to zoom the visible section of the microplate grid from displaying the whole plate up to displaying only one well.

Use the zooming controls shown at the bottom right of the grid to change the zoom factor (in Percent). You can either press the Zoom In or the Zoom Out buttons to zoom into the grid or out of the grid in predefined steps (25 %) or by entering a zoom factor in the entry field. The entered value will be adjusted to display only whole wells.

To reset the view to the whole plate (100%) setting, press the button.

3.3.5 Exclude Wells
If there are outliers within your test run data, you can exclude these wells from the evaluation by applying a toggle to the usage state of the wells you do not wish to use. Wells can be set to be excluded, or these unused wells can be set to be used again by pressing the Ctrl-T keys on your keyboard or by clicking on the right mouse key to use the popup menu, after selecting the wells in the Microplate View. You can also find a Toggle Well command in the Working Area group on the View tab of the Ribbon.

Unused wells are displayed with diagonal gray stripes. Only the raw data values and the layout values are displayed (also in gray).

3.3.6 Microplate Bar Chart
You can create two kind of bar charts from the data currently displayed in the microplate view.

1. A bar chart form the whole microplate (select Create Microplate Bar Chart from the popup window):

The chart displays a bar for each measured well in the microplate view according to the value for this well based on the selected data. If the currently displayed microplate view contains more than one data row, you can change between the different data row, using the drop down selection control on the bottom of the dialog. You can adjust the 3D settings of the chart, using the 3D% and the Zoom slider. To change the rotation of the chart, you can use the mouse by clicking into the chart and move the mouse. To change further settings, click the Settings... button. To print the chart, click on the print button.

2. A bar chart based on the selected wells (select Create Bar Chart from selected wells from the popup window):
The chart displays a bar only for the selected wells, but also one for each selected data row. You can swap the x and z axis in the chart with the Swap Selection and Well Axis button. You can adjust the settings of the bar chart and print it using the same controls as for the microplate bar chart, described above.

### 3.3.7 BMG LVis Micro Drop Plates

If the opened test run was measured using the BMG LVis Micro Drop plate, the displayed grid contains only the two used columns 10 and 11 of the plate:

<table>
<thead>
<tr>
<th>Wells</th>
<th>Replicates</th>
<th>Content</th>
<th>Group</th>
<th>Wavelength</th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td>1</td>
<td>C</td>
<td>C</td>
<td></td>
</tr>
<tr>
<td>C</td>
<td>1</td>
<td>C</td>
<td>C</td>
<td></td>
</tr>
<tr>
<td>C</td>
<td>1</td>
<td>C</td>
<td>C</td>
<td></td>
</tr>
<tr>
<td>C</td>
<td>1</td>
<td>C</td>
<td>C</td>
<td></td>
</tr>
</tbody>
</table>

The first three columns are predefined with the row and column name of the well and the content of the well. If there are groups defined in the layout, a fourth column with the group name is also shown. To the right of the predefined columns, the columns corresponding to the data nodes as selected in the navigation tree are displayed.

The legend under the table shows a description of the selected data nodes. The color of the selected row in the navigation tree is displayed in the legend before the corresponding line and is also used as background color for the header of the appropriate column.

If groups are defined in the layout, the background of the row will be drawn in the color unique to the associated group.

If a well is not used (see chapter 3.3.5: Exclude Wells) the row of the well is shown with a light gray background and a dark gray text color.

You can order, filter or move each data column in the table. The fix columns WellRow, WellCol, Content and Group cannot be moved. Grouping is only possible with the Column Content and Group. You can also not move columns into or inside a column sequence (columns with the same header color are a sequence of cycles or wavelength and cannot be divided or resorted). You can hide the fix columns and the column WellRow and WellCol can also be merged in one column WellName (see Tableview Settings).

More information is given about common table functionality in the chapter 2.2: Group and Filter Test Runs .

The column Content has a special filter function. Move the mouse over the column header and press the appearing arrow button. The filter list for the column opens (see right image).

The filter (Replicates only once) displays only the first well of each replicate series. This filter is useful if the data to display are based on replicate statistics.

There are further controls shown above the table:

- Export the table to excel (you must have installed an excel version on your computer). See chapter 3.2.1: Export Data.
- Export the table into a text file. The data of the table are stored in the comma separated value (CSV) format (See chapter 3.2.1: Export Data).
- Open the Table View Settings page to change further table view options.

**Wavelength:** This option appears only for spectrum scan test runs and is only enabled if in the Select a Wavelength group box is nothing selected. Select which wavelength you want to display.

**Note:** If you have a lot of spectrum data (many wells and a large measured spectrum especially in combination with kinetic data), the creation of the table with spectrum or blank corrected spectrum data may take some time (a progress bar with an abort button will appear!)

**Select a Wavelength group:** This control appears only for spectrum scan test runs. With the drop down list, you can select the wavelength range you want to see in the table. If at least one entry is checked, a column for each wavelength of the selected ranges is created (only if the selected data contains spectral data). The wavelength is shown in the Wavelength row. You can combine the selection of the ranges or you can select All Wavelengths to display all wavelengths. To see only one wavelength in the table, deselect all selected entries and select the wavelength with the Wavelength control on the left.
Cycle: This option appears only for kinetic test runs and is only enabled if the All cycles/Intervals box is not checked. Select which cycle/interval you want to display.

Select a cycle/interval group: This control appears only for kinetic test runs. With the drop down list, you can select the cycles/interval ranges you want to see in the table. If at least one entry is checked, a column for each cycle/interval of the selected ranges is created (only if the selected data contains cycles/interval). The header of the column is expanded with the cycle/interval number, if detailed header is not checked. The time value is shown in the Time row. You can combine the selection of the ranges or you can select All Cycles/Intervals to display all cycles/Intervals. To see only one cycle in the table, deselect all selected entries and select the cycle with the Cycle control on the left.

With the table view option 'grouped by kinetics' you can decide, if the kinetic data should be displayed successively for the selected data (like displayed above) or if the data should be ordered by selection followed by cycle:

Cycle: This option appears only for kinetic test runs and is only enabled if the All cycles/Intervals box is not checked. Select which cycle/interval you want to display.

Popup Window
The Table View page has a popup menu that can be reached by pressing the right mouse button when the mouse is over the table:

1. Don’t use the selected well(s) (see Exclude Wells)
2. Reuse excluded wells (see Exclude Wells)

3.5 Well Scan Area Statistic Table
This page is only visible for well scan test runs with defined areas.

The area statistics view page displays the statistical data of all defined areas in a table with a row for each well. Each statistic value is represented by a table column.

You can order, filter or move each column in the table. Grouping is only possible with the Column Content and Group.

You can hide certain columns if you click on the hide item of the table and select the columns you want to hide or show:

More information is given about common table functionality in the chapter 2.2: Group and Filter Test Runs .

There are further controls shown above the table:

- Export the table to excel (you must have installed an excel version on your computer). See chapter 3.21: Export Data.

- Export the table into a text file. The data of the table are stored in the comma separated value (CSV) format (See chapter 3.21: Export Data).

3.6 Common Chart Functions
The subjects described in this chapter apply to all four kinds of chart used in MARS.

The signal curves chart (available for kinetic test runs), the spectrum curves chart (only for spectrum measurements), the standard fit curves chart (available after a performed standard calculation) and the enzyme kinetic fit curves chart (available after a performed enzyme kinetic calculation).

All these charts contain the following elements and functions:

- A chart with at least one X-axis and one Y-axis and selected curves in it
- A legend explaining the displayed curves
- A control box to hide or show the legend
- Crosshair functionality
- Zooming possibilities
- Two windows to change the settings of axes and curves.
The chart title and the title font can be changed on the Chart Title tab of the chart settings dialog box. Click Chart Settings..., select the Chart Title tab and enter the desired settings (see chapter 3.9: Chart Title Settings).

3.6.1 Chart Axes and Curves

A chart consists of one X axis and one or more Y axes (e.g. the signal curves chart has Y axes for each signal curve with a different unit value). If the chart has more than one Y axis, they are shown as different charts one on top of the other. Each axis can be individually customized:

Each curve in the chart has its own color and the data points of the curve (if it is a data curve and not a calculated fit curve) have an initial shape. The shapes of the data points belonging to the same Y axis are equal but the shapes of the data points of different Y axes are different (like the shapes of the two curves in the screen shot above).

Click on the curve or click on the associated legend entry to select a curve in the chart. The selected curve has a bold line and two enclosing brackets (<...>) in the legend. The corresponding node in the navigation tree and - if visible - the corresponding well node in the content filter tree will also be selected.

You can change the color and the style of the curve with the chart settings dialog box (pressing the Chart Settings... button, see chapter 3.8: Change Chart Curve Settings).

You can define each axis according to the start and stop value, the increment value, the name, the scaling (logarithmic or linear) and the number format settings for the displayed axis labels, by opening the chart settings dialog box to change these attributes (see chapter 3.7: Change Settings of a Chart Axis).

The title of the chart can also be changed in the chart settings dialog box.

Chart Legend

The chart legend contains an entry for each displayed curve or data point series in the chart describing the curve.

To hide the legend, uncheck the Show Legend check box.

3.6.2 Changing chart legend entries

You can change the text of legend entries manually. Click on the Edit Legend item in the chart popup menu or open the chart settings dialog box select the Legend tab and click the Edit legend contents button to open the Edit Legend Entries dialog box:

Click in one of the entry fields and enter the desired legend entry. The legend entry is part of the test run setting. Save the test run settings, to make your changes persistent.

Note: There is a maximum of 80 signs you can enter for each legend entry.

You can also change the font of legend entries, the legend title and the legend position in the chart settings dialog box. Select the Legend tab and define the desired settings (see chapter 3.10: Chart Legend Settings).

3.6.3 Crosshair

The crosshair consists of a horizontal and a vertical line on the chart. The intersection of the two lines is always a point on the selected curve. Check the Show crosshair for active curve to display the crosshair. The x and y values of the intersection point are displayed in the two fields of the crosshair control group. To set a position for the crosshair to a given x value, enter that value into the entry field for the x intersection point.

You can move the crosshair along the curve in x direction by dragging its vertical line with the mouse and dropping it at the desired position. There are two modes moving the crosshair along the curve:

- **Lock to data**: The crosshair jumps from one measured data point to the next data point when you move it.
- **Lock to curve**: The crosshair moves also between data points along the curve (linear connection between adjacent data points).

Change the mode by clicking on the corresponding radio button.

3.6.4 Chart Popup Menu

Each chart comes with a popup menu you can open by clicking the right mouse button.

You can insert up to five comments at the current mouse position (see chapter 3.6.6: Chart Comments)

The menu items for zooming apply to the zoom functionality of the chart (see chapter 3.6.5: Zooming)
Click Edit Legend, to change the text of the chart legend entries. You can create a bitmap out of the chart and save it into a *.bmp file on your file system. Depending on the usage of the created bitmap you can create a normal or a high resolution bitmap.

### 3.6.5 Zooming

It is easy to zoom in on a chart using the mouse: using the left mouse key drag the cursor from the top left of the chosen area out to the bottom right corner of the zoom area. When the mouse button is released the chart will then zoom into the highlighted area.

**Note:** Zooming using the mouse in the signal curve window is not possible if ranges are displayed (see chapter 3.11: Signal Curve).

There are zooming buttons on the right side of the chart that can also be used. Clicking on these buttons will zoom into the center of the chart in predefined steps. If you use the Zoom In (+) item on the popup menu, the position of the mouse is used as new center of the chart before zooming.

To move the zoomed area, press and hold the shift key on the keyboard and hold the left mouse button over the chart. To change the positioning of the zoomed area, press the left mouse button whilst holding down the shift key and move the mouse.

To reset the chart to its normal size, double click on the chart or press the button.  

**Note:** Resetting the zoom re-establishes the state before zooming, but will not change start and end values of the axis to the initial values if you've changed them with the axis settings window!

### 3.6.6 Chart Comments

A chart can have up to five individual comments. To add a new comment, move the mouse to the position on the chart where the upper left corner of the comment should be placed and press the right mouse button. Use the Insert Comment on Mouse Position item on the appearing popup menu to add the comment. Enter the text and click outside the comment window after entering the desired comment.

Chart comments can be removed by moving the mouse over the comment and press the appearing button.

### 3.7 Change Settings of a Chart Axis

To change the axis scaling of an axis of any displayed chart (signal curve chart, spectrum chart, standard curve chart or enzyme equation chart), select the Formats and Settings tab on the Ribbon. On the Axis Settings group, you find two sub groups for the Y axes and the X axis. If the chart has more than one Y axis, use the drop down list Y Axis, to select the accoring axis. Click the Lin or Log button, to change between linear and logarithmic axis scaling. Use the Auto Scale button to change between automatic axis scaling and user defined minimum and maximum axis scaling. The minimum and maximum values of the axis can then be entered in the Min and Max entry fields.

**Note:** You have to press the Enter key ( ) on the keyboard to apply the entered minimum or maximum value!

If the Auto Scale button is pressed (highlighted), you can click the Start with 0 button, to force the axis to start with zero, but to calculate the maximum value automatically. For a detailed description of all available settings, see the table at the end of this chapter.

<table>
<thead>
<tr>
<th>Visible</th>
<th>Uncheck this control if you want to hide the axis.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select axis</td>
<td>This entry field is only shown if the Vertical Axis(Y) group was selected. Select the Y-Axis you want to customize.</td>
</tr>
<tr>
<td>Title/Unit</td>
<td>Displays the title of the axis. To change the title, enter the new title in this field. Enter a unit into the unit field. If a unit is entered the title will be suplemented with &quot;in Unit&quot; (where Unit is replaced by the entered unit).</td>
</tr>
<tr>
<td>Font</td>
<td>Shows the used font for the Axis title and labels. Click Change to change the font.</td>
</tr>
<tr>
<td>Scale Settings</td>
<td>Controls in this group box define the scaling settings of the axis.</td>
</tr>
</tbody>
</table>

If you want to change further settings of any chart just click on the appropriate axis in the chart. Alternatively you can click the Chart Settings button above the chart or the dialog launcher button in the Axis Settings group on the Formats and Settings tabs and select the tab of the axis you want to change.

The Chart Axis and Series Settings dialog box opens and lets you customize all settings of the axis. Select the group of axes you want to customize with one of these tabs:

- Vertical Axis(Y): all Y axes (one or more)
- Horizontal Axis(X): the X axis (only one)
- Depth Axis (Z): the Z axis (only available in spectrum 3D charts).
3.8 Change Chart Curve Settings

The series settings page lets you customize the settings of any curve in the chart. Click on the Chart Settings... button above the chart and select the Series tab:

For three dimension charts (3D charts) the settings part of the window looks different:

Select the curve or the group of curve you want to change:
If you want to make changes for all curves, select the All curves radio button. If All curves is selected, a check box appears at the top of each settings group. Click the check box of the kind of settings (color, line or point style) you want to change for all displayed curves.

If you want to change the settings of a single curve, click the Single curve radio button and select the curve you want to change using the drop down list control beside the radio button.

The changes will be overtaken only if you press the Apply button of the dialog box.

Changeable settings:

<table>
<thead>
<tr>
<th>Color</th>
<th>Define the color of the line and data points. If Default is checked, the color is selected automatically (only available for 2D charts and if Single curve is selected).</th>
</tr>
</thead>
<tbody>
<tr>
<td>For 3D charts only:</td>
<td></td>
</tr>
<tr>
<td>Use Color Range</td>
<td>Select this control to define a color range for the shape from a start color to an end color.</td>
</tr>
<tr>
<td>Start Color</td>
<td>Define the start color of the three dimension shape color range. The color of the shape fades from the start color for the highest values to the end color for the lowest value (only available for 3D charts).</td>
</tr>
<tr>
<td>End Color</td>
<td>Define the end color of the three dimension shape color range. The color of the shape fades from the start color for the highest values to the end color for the lowest value (only available for 3D charts).</td>
</tr>
<tr>
<td>Use Palette</td>
<td>Select this control to define the color for the shape based on a color palette. Use the drop down control to select the desired color palette.</td>
</tr>
<tr>
<td>Lines</td>
<td>Defines the look of the line between data points.</td>
</tr>
<tr>
<td>Line style</td>
<td>Select the style of the line between the data points:</td>
</tr>
<tr>
<td>Width</td>
<td>Enter the desired line width or adjust the desired line width with the track control.</td>
</tr>
<tr>
<td>Points</td>
<td>Defines the look of the data points of the curve/data series (not enabled for calculated curves like the standard curve and not available for 3D charts).</td>
</tr>
<tr>
<td>Visible</td>
<td>Data points are visible if this check box is checked.</td>
</tr>
<tr>
<td>Point shape</td>
<td>Select the shape of the data points of the curve/data series:</td>
</tr>
</tbody>
</table>
3.9 Chart Title Settings

The Title and the used font of the chart title can be changed. Click on the Chart Settings... button above the chart you want to change and select the Chart Title tab on the chart settings dialog box.

Note: The changes will be overtaken only if you press the Apply button. To reset all applied changes to default settings, press the Reset to Default Settings button

Changeable settings:

| Visible | If checked, the chart title is visible. |
| Title   | Change the chart title here. |
| Font    | The used font is displayed here. To change the font, click the Change... button |

3.10 Chart Legend Settings

The Title and the used font of the chart legend can be changed. Click on the Chart Settings... button above the chart you want to change and select the Chart Title tab on the chart settings dialog box.

Note: The changes will be overtaken only if you press the Apply button. To reset all applied changes to default settings, press the Reset to Default Settings button

Changeable settings:

| Visible | If checked, the chart legend is visible. |
| Custom Legend Position | Define the position of the legend (see section below) |
| Title | Change the legend title here or leave it empty if no title is wanted. |
| Font | The used font is displayed here. To change the font, click the Change... button |
| Edit legend contents | Click this button to change the entries of the chart legend. Details are described in Common Chart Settings, chapter Changing chart legend entries. |

If the Custom Legend Positioning is checked, the legend is drawn upon the chart and can be moved to any position over the chart using the mouse (move the mouse cursor over the chart to drag it and release the mouse button to drop it at the desired position).

If the check box is unchecked, the legend will be displayed beside the chart (defaulting to the right side of the chart). The chart size will be reduced so that the legend and the chart will both fit on the screen. You can change the position of the legend to the four places:
- on top of the chart
- left side of the chart
- right side of the chart
- under the chart

Change the position using the mouse by dragging it to the new position and then drop it.

3.11 Signal Curve

In case your test run contains kinetic data it can be viewed by clicking on the Signal Curve tab in the working area. This view can also be obtained by double clicking on a well in the Microplate View, when the curve view mode is active.

The signal curve chart will plot the kinetic data for all data nodes selected in the navigation tree against time. Only the data of wells either selected in the Microplate View or in the content filter tree, will be displayed. The data points of one well in the chart are connected by a thin linear line. The line can be removed in the curve settings window.

Note: If there is no node or well selected the working area will appear empty!

In addition to the common chart functions (zooming, crosshair function, axis scaling...), the chart for the signal curves will also display user defined ranges. Each range is shown as a dashed blue rectangle with the name and the start and stop cycle/interval as a caption. If the range represents a baseline section of the kinetic (see chapter 4.4.4: Baseline Corrections), the border of the range will be red. To select a range, click onto the range using the mouse, the selected range will then change to a non-dashed bold rectangle. It is only possible to select one range at a time.

If performing the kinetic calculation Time to threshold, a red horizontal line will appear in the chart to mark where the threshold position is on the Y axis.

If performing the kinetic calculation Maximum of slope, a line with that slope in the same color as the series will appear. The line intersects the series at the time position of the maximum slope.
The popup menu for the signal curve chart is expanded to include special range functions (see also the section 3.11.1: *Range Functions in the Chart*):

![Range Functions in the Chart](image)

To zoom in the chart using the mouse as described in the chapter 3.6.5: *Zooming*, the *Mouse Zooming* mode must be activated using the respective buttons available under the chart. Whilst using the zooming feature the ranges selected will be hidden, to see the ranges again, they can be activated by clicking on the *Show Ranges* button.

**Note:** The 'Mouse Zooming mode' can also be used to temporarily hide the ranges, if a better look of the data needed.

### 3.11.1 Range Functions in the Chart

The chart can be zoomed to the size of the active range using the *Zoom in Active Range* function found in the charts popup menu. This will show only the data lying within the defined range (including the range borders).

To change a range in the chart, you first have to select it. In the next three sections it is explained how to change the ranges in the chart directly. In addition you can view, add and change ranges with the range window.

The *Change Range* button under the chart opens the range window as well as the *Ranges* button in the *Data Reduction* group on the *Home* tab of the Ribbon. (See chapter 4.1: *Ranges*).

### Changing Range Position

Move the mouse cursor into the active range (the mouse cursor will then change to a small hand point). Click into the range using the right mouse button and hold the button. Move the mouse and the range will follow the mouse. Leave the mouse button when the range has reached the desired position.

### Changing Range Size

To change the size of the active range (changing the first or final cycle/intervals used in the range) you must first move to the border line that you would like to change. When the mouse is over the border, the mouse cursor will change to an icon with two arrows (<<>). Click the left mouse button and hold it, moving the mouse to the position of the range start / stop cycle/interval and release the mouse button.

**Note:** If a range is changed that has already been used to perform any calculations (like a kinetic calculation), the calculations will be updated in line with the new range details. This will in turn also influence any calculation based on the updated calculations. Recalculation may mean that there is a small delay after adjusting the range borders (this will be indicated with a message box).

### Adding and Deleting Ranges

When opening a kinetic test run for the first time, at least one range will be created by default (read more about predefined ranges in the chapter 4.1.1: *Predefined Ranges*). If you want to add a further range press the [New Range] button or select the *Add Range* item from the popup menu by pressing the right mouse key in the active chart.

The default range shown in the chart will be already selected. Its borders are set from the first cycle/interval to the last cycle/interval, the borders and their position can then be changed as described in the Changing Range Size and Changing Range Position sections.

To delete a range, select the *Delete Active Range* item from the popup menu. A range that has been used to perform a calculation will not be deleted unless the calculation is deleted first.

#### 3.11.2 Show Injection Markers

If the test run has injections, you can show small markers for each injection on the time axis of the signal curve.

The position of the marker on the axis is equivalent to the start time value of the corresponding injection cycle.

To show the markers, check the control *Show Injection Markers* in the *Chart* group in the *View* ribbon menu.

#### 3.11.3 Show Error Bars

Above the chart there is a further control available to show error bars in the chart. The check box can be checked, if replicates are defined in the layout and the displayed signal curve is based on an average calculation over replicates.

### 3.12 Spectrum Curve

The spectrum curve chart will be available if your test run contains spectra data. The chart can be accessed by clicking on the *Spectrum* tab on the working area or by double clicking on a well in the Microplate View, if the spectrum view mode is active.

The spectrum curve chart plots the spectrum data of all selected spectrum nodes in the navigation tree against lambda (wavelength). Data will be shown for all wells which have been selected in the Microplate View or in the content filter tree. The data points of one well are connected by a thin line. It is possible to remove the line using the Curve Settings window.

For each added discrete wavelength a dashed vertical line at the position of the lambda value on the X axis will be displayed. The color of the dashed line relates to the natural color of the lambda value. If you don't want to see the lines shown in the lambda-color you can display them in gray by changing the corresponding setting in the Spectrum Display Settings window.

**Note:** If there is no well or node selected, the working area will appear empty!
background or to select a white background, use the Spectrum Display Settings window.

In addition to the common chart functions (zooming, crosshair function, axis scaling...) it is also possible within this chart to add discrete wavelength data to the test run (see next section: Adding a Discrete Wavelength) and the chart will also display user defined ranges.

Each range is shown as a dashed blue rectangle with the name and the start and stop wavelength as a caption. To select a range, click onto the range using the mouse, the selected range will then change to a non-dashed bold rectangle. It is only possible to select one range at a time.

If performing the spectrum calculations Local minima, Local maxima or Inflection points, a black vertical line for each calculated minima, maxima of inflection point at its wavelength position will be displayed in the chart.

The popup menu for the spectrum curve chart is expanded to include special range functions (see also the section 3.11.1: Range Functions in the Chart) and functions to add discrete wavelength.

To zoom in the chart using the mouse as described in the chapter 3.6.5: Zooming, the Mouse Zooming mode must be activated using the respective buttons available under the chart. Whilst using the zooming feature the ranges selected will be hidden, to see the ranges again, they can be activated by clicking on the Show Ranges button.

Note: The 'Mouse Zooming mode' can also be used to temporarily hide the ranges, if a better look of the data needed.

Read more about range functions in the chart in the appropriate section in the signal curve chapter as the described function is also valid for the spectrum curve (section 3.11.1: Range Functions in the Chart).

### 3.12.1 Adding, Changing or Removing Wavelengths

Note: At least one discrete wavelength from an absorbance spectrum will be needed to perform calculations other than spectrum calculations or spectrum kinetic calculations, as these calculations are not possible using the full spectrum data.

Note: If there is a combined excitation and emission scan, each discrete wavelength is assigned to either the excitation or the emission scan!

To add one or more new discrete wavelength to the test run, press the Wavelengths... button shown under the chart or open the popup menu and select one of the offered items Add Wavelength, Add Wavelength at Mouse Position or Add Wavelength at Crosshair Position. You can add as many wavelengths as needed (The maximum number allowed = the total of all measured data points).

If Add Wavelength at Mouse Position or Add Wavelength at Crosshair Position was selected, a wavelength will be added at the current x-axis position of either the mouse or the vertical crosshair line.

The following window will be shown if the Wavelengths... button or Manage Wavelengths in the Data Reduction group of the Home ribbon menu was pressed:

![Manage Wavelengths](image)

The window offers two ways to manage wavelengths:

1. **Automatic wavelength detection:**

If you want to add one or more wavelength at maxima or minima of the selected spectrum curve, select the according radio control and press the Apply button. The selected spectrum curve can be changed if you press the button and open the spectrum curve selection control:

![Wavelength Selection](image)

The control is closed if you open the window from the spectrum curve page with a selected spectrum curve. If you open the window from any other page, using the menu entry Manage Wavelengths in the Data Reduction group of the Home ribbon menu, the control is already opened.

The from and to Lambda entry fields are used to define the range on which the minima and maxima calculations are based on. If the spectrum chart is visible, the current X-Axis settings are used as preset values for this range.

The following calculations are based on the selected spectrum curve:

<table>
<thead>
<tr>
<th>Operation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>at next local minimum</td>
<td>Searches for the minimum value of the active spectrum curve in the defined lambda range. If there is a discrete wavelength selected already at that point, the next higher minimum will be found and selected.</td>
</tr>
<tr>
<td>at next local maximum</td>
<td>Searches for the maximum value of the active spectrum curve in the defined lambda range. If there is a discrete wavelength selected already at that point, the next lower maximum will be found and selected.</td>
</tr>
<tr>
<td>add Wavelengths for all local minima</td>
<td>Tries to find out all minima of the active spectrum curve. Adds a wavelength for each found local minima. A local minimum is defined as a significant lower value between higher values.</td>
</tr>
<tr>
<td>add Wavelengths for all local maxima</td>
<td>Tries to find out all maxima of the active spectrum curve. Adds a wavelength for each found local maxima. A local maximum is defined as a significant lower value between higher values.</td>
</tr>
</tbody>
</table>
The added wavelengths will appear in the Change / Add / Remove wavelengths manually section and can be changed there:

2. Change, Add or Remove Wavelength(s):

For each discrete wavelength already added, an entry field and a delete button is shown. The value can either be changed or the discrete wavelength can be removed from the test run with the delete button.

An empty entry field is show (with no delete button behind) to enter new discrete wavelength. After pressing the add button, the wavelength will be added and the empty entry field can be used to enter further wavelengths. If the crosshair is visible in the spectrum chart, the X value of the crosshair can be used as default value and the empty entry field is preset with this X value. To delete all wavelengths at once, press the Delete All button.

Note: Press the OK button to apply the changes to the test run.

3.12.2 Change the Lambda Value of a Discrete Wavelength

It is possible to change the lambda value of an added wavelength directly in the chart:

- Move the mouse over the wavelength line in the chart, the mouse cursor will then change to two arrows (<>).
- Click and hold the left mouse button.
- Move the line to the new position and release the mouse button.

Alternatively you can use the Manage Wavelength window (see chapter 3.12.1: Adding, Changing or Removing Wavelengths above) to change the lambda value of one or more added wavelength(s) at once.

Note: If a wavelength is changed that has already been used to perform any calculations, the calculations will be updated in line with the new wavelength details. This will in turn also influence any calculation based on the updated calculations. Recalculation may mean that there is a small delay after adjusting the wavelength (this will be indicated with a message box).

3.12.3 Deleting a Discrete Wavelength

To delete a discrete wavelength, even after performing calculations, open the popup menu of the spectrum chart and select the menu item Remove Wavelength, or select the raw data node for that wavelength in the navigation tree and press the Del key on your keyboard (this is the same as selecting the Delete menu item in the navigation tree popup or the Delete Node button in the Navigation group on the View tab of the Ribbon).

To delete more than one wavelength at once, you can also use the Manage Wavelength window (see chapter 3.12.1: Adding, Changing or Removing Wavelengths above).

3.12.4 Spectra and Kinetics

If the measurement of spectra comes with a kinetic, additional controls appear above the chart:

Select the displayed spectra for certain cycles with the drop down menu on the top right side. You can select one cycle, all cycles or only certain cycles to compare them in one chart.

3.12.5 Combined excitation and emission spectra

If the measurement is an excitation and emission scan, you can also change to a three dimension presentation where one axis is the excitation wavelength and the depth axis is the emission wavelength. Thee three dimension matrix is calculated based on the two spectra:
To see the fit results of all displayed standard curves, open the fit result window with the `Fit Results` button on the top right corner of the chart.

In addition to the common chart functions (zooming, crosshair function, axis scaling...), the standard curve chart has a check box bar to select or deselect the fit results for single groups. This bar will appear only if groups were defined in the layout. To select all groups or to deselect all groups with one click, use the two buttons Select All Groups and Deselect All Groups above the chart.

Check or uncheck the box of the group you want to see or hide.

If more than six groups are defined, the check boxes are replaced by a drop down menu to select the desired groups.

The popup window of the standards curve comes with additional entries to modify the fit:

![Fit Methods](image)

- **Calculates Spectra**
  
  For each performed spectrum calculation type (difference or ratio) between two cycles, an additional chart with its own Y axis is drawn:

![Spectra Chart](image)

### 3.13 Standard Curve

The standard curve chart option will be available if you have performed a standard calculation. To view the chart, click on the **Standard Curve** tab in the working area.

The standard curve chart will plot the fit result curves and the standards for all selected standard fit nodes in the navigation tree against concentration. The color and style of the curves and standards can be changed using the Curve Settings window.

**Note:** If nothing is selected, the working area will appear empty!

![Standard Curve Chart](image)

When the standard curve chart is visible, the detailed window under the navigation tree will be visible instead of the content filter tree. The detailed window shows the fit parameters and fit results of the selected data node in the navigation tree.

If the chart contains a 4-Parameter standard fit and the crosshair is shown, you can see the EC or IC value of the crosshair position beside the Y value of the crosshair below the chart. Enter the EC or IC value you want to see and the crosshair will move to that position (if it is in the charts range).

**Note:** Use the 'lock to curve' setting to get the exact position.

### 3.13.1 Error Bars, Replicates of Standards, Confidence Band and Recalculated Values

Above the chart there is a further control available to show error bars, confidence band, replicates of standards and recalculated values in the chart.

Open the drop down list and check on of the available controls:

- **Show Error Bars:** error bars will be displayed for the standards.
- **Show Confidence Band:** the calculated confidence band will be displayed for each standard curve.
- **Show Replicates:** if the replicates are defined for the standards, the replicates can be displayed for each standard.
- **Show all recalculated values:** display the recalculated values of all wells on the fitted curve (as gray points on the curve).
Show only recalculated Samples: display the recalculated values of the samples only on the fitted curve (as gray points on the curve).

In this chart error bars, replicates and confidence band are displayed:

The parameters for the calculation of the confidence intervals (e.g. CI = 95%) are defined in the standard calculation dialog (see chapter 4.10: Standard Calculation). The confidence band is also defined by the confidence interval settings.

To view the error bars the following conditions must be fulfilled:
- You must have defined replicates for your standards in the layout of the test run.
- The Y-Axis scaling is not logarithmic.
- The standard deviation of the replicates may not be zero.
- The standard fit may not have a user generated replicate statistic in its base processes (see chapter 4: Perform Calculations).

If recalculated values are displayed, the values are marked with the well name (and the sample ID for the well, if defined):

To hide the marks, open the standard curve popup menu (press the right mouse button) and select Hide Value Labels.

3.13.2 Fit Result Window

To view the fit result parameters of all displayed standard curves, press the Show fit Results button and a window showing the results will open:

The window contains a page for each performed standard fit. To open a page of a standard fit, click on the appropriate tab on the top of the window.

The first line of the window displays the applied fit formula.

The fit results are organized in a kind of table, where the columns represent the groups from the layout and the rows represent the different wavelength data.

Each result on its own has a small table whose rows represent the parameters of the fit. The parameters shown are dependent upon the fit performed. The parameter qualifying the fit result is \( r^2 \). Its associated row is highlighted with a blue background.

Check Display confidence interval values to display also the values for the confidence interval.

To export all results to Excel, press the button.

If the fit method is a 4-Parameter fit, you can add additional EC/IC values to the fit result parameters. Enter the desired value in the control on the right top of the window and press the apply button.

To remove an added EC/IC value from the result parameter list, click the cross button beside the parameter:

You can enter additional Y values to get the calculated x values and add this value to the fit parameter list. If the value cannot be calculated you can get one of the following results:

<table>
<thead>
<tr>
<th>Text</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>n.a.</td>
<td>Not available - recalculation not possible</td>
</tr>
<tr>
<td>&lt;&lt; std range</td>
<td>The calculated concentration value for this Y value is under the defined limit for this calculation method. See Limitations for Recalculated Concentrations table.</td>
</tr>
<tr>
<td>&gt;&gt; std range</td>
<td>The calculated concentration value for this Y value is above the defined limit for this calculation method. See Limitations for Recalculated Concentrations table.</td>
</tr>
<tr>
<td>&lt;&lt; Y range</td>
<td>The Y value is either under the domain of the fit or under the defined limit for this calculation method. See Limitations for Recalculated Concentrations table.</td>
</tr>
<tr>
<td>&gt;&gt; Y range</td>
<td>The Y value is either above the domain of the fit or above the defined limit for this calculation method. See Limitations for Recalculated Concentrations table.</td>
</tr>
<tr>
<td>ambiguous</td>
<td>The Y value is ambiguous, that means that it fits to more than one concentration value.</td>
</tr>
</tbody>
</table>
After adding one or more Y-Values to the fit result list, you can remove them with the delete button beside the parameter.

3.14 Enzyme Kinetic Fit Curves

The enzyme kinetic curve chart option will be available if you have performed an enzyme kinetic calculation. To view the chart, click on the Enzyme Kinetic Fit(s) tab in the working area.

Read more about how to use the MARS Data Analysis software for the determination of Km and Vmax in chapter 4.16: Enzyme Kinetic Calculations.

The enzyme kinetic fit chart will plot the result curves of enzyme kinetic calculations such as Michaelis-Menten Plot, Lineweaver-Burk Plot etc. for all selected enzyme kinetic fit nodes in the navigation tree. The color and style of the curves and standards can be changed using the curve settings dialog box.

**Note:** If nothing is selected, the working area will appear empty!

![Enzyme Kinetic Fit Curve Chart]

When the enzyme kinetic fit chart is visible, the detailed window under the navigation tree will be visible instead of the content filter tree. The detailed window shows the fit parameters and fit results such as Vmax and Km of the selected data node in the navigation tree.

There can be different types of enzyme kinetic fits. Each type is displayed in its own chart. To change between the chart views, use the arrow buttons up ▲ and down ▼ on the right side of the chart to select the previous/next chart. You can also click directly on the data node of an enzyme kinetic equation in the navigation tree to open the according chart.

To see the fit results of all calculated enzyme kinetic fits, open the fit result window with the \[\text{Fit Results} \] button on the top right corner of the chart.

In addition to the common chart functions (zooming, crosshair function, axis scaling,...), the enzyme kinetic fit chart has a check box bar to select or deselect the fit results for single groups. This bar will appear only if groups were defined in the layout.

Check or uncheck the box of the group you want to see or hide.

If more than six groups are defined, the check boxes are replaced by a drop down menu to select the desired groups.

If a Michaelis-Menten chart is displayed, a line for the calculated Vmax and Km value can be displayed in the chart. Select the View tab in the ribbon and activate the Show Km and Vmax in plot control on the Chart group to add the lines to the chart.

3.14.1 Error Bars

Above the chart there is a further check box available: Show Error Bars.

- You must have defined replicates for your standards in the layout of the test run.
- The standard deviation of the replicates may not be zero.
- The enzyme kinetic fit may not have a user generated replicate statistic in its base processes (see chapter 4: Perform Calculations).

3.14.2 Fit Result Window

To view the fit result parameters of all calculated enzyme kinetic fits, press the Show fit Results button and a window showing the results will open:

The window contains a page for each performed fit and displayed fit. To open a page of a fit, click on the appropriate tab on top of the window.

The first line of the window displays the applied fit formula.

The fit results are organized in a kind of table, where the columns represent the groups from the layout and the rows represent the different wavelength data.

Each result on its own has a small table whose rows represent the parameters of the fit. The parameters shown are dependent upon the fit performed. The parameter qualifying the fit result is \( r^2 \). Its associated row is highlighted with a blue background.

To export all results to Excel, press the \[\text{Excel} \] Button.

3.15 Binding Kinetics Fit Curves

The binding kinetics curve chart option will be available if you have performed an kinetic rate equation. To view the chart, click on the Binding Kinetics Curve tab in the working area.

The color and style of the curves and standards can be changed using the curve settings dialog box.

**Note:** If nothing is selected, the working area will appear empty!

When the binding kinetics fit chart is visible, the detailed window under the navigation tree will be visible instead of the content filter tree. The detailed window shows the fit parameters and fit results such as \( k_a \), \( k_d \), \( R_{max} \) and \( r^2 \) of the selected data node in the navigation tree.

To see the fit results of all calculated enzyme kinetic fits, open the fit result window with the \[\text{Fit Results} \] button on the top right corner of the chart.
In addition to the common chart functions (zooming, crosshair function, axis scaling...), the enzyme kinetic fit chart has a check box bar to select or deselect the fit results for single groups. This bar will appear only if groups were defined in the layout.

Check or uncheck the box of the group you want to see or hide.

If more than six groups are defined, the check boxes are replaced by a drop down menu to select the desired groups.

### 3.15.1 Fit Result Window

To view the fit result parameters of all calculated fits, press the Show fit Results button and a window showing the results will open:

The window contains a page for each performed and displayed fit. To open a page of a fit, click on the appropriate tab on top of the window.

The first line of the window displays the applied fit formula.

The fit results are organized in a kind of table, where the columns represent the groups from the layout and the rows represent the different wavelength data.

Each result on its own has a small table whose rows represent the parameters of the fit. The parameters shown are dependent upon the fit performed. The parameter qualifying the fit result is $r^2$. Its associated row is highlighted with a blue background.

<table>
<thead>
<tr>
<th>Text</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>n.a.</td>
<td>Not available - recalculation not possible</td>
</tr>
<tr>
<td>&lt;&lt; Y range</td>
<td>The input value is either under the domain of the fit or under the defined limit for this calculation method.</td>
</tr>
<tr>
<td>&gt;&gt; Y range</td>
<td>The input value is either above the domain of the fit or above the defined limit for this calculation method.</td>
</tr>
</tbody>
</table>

To export all results to Excel, press the ![Excel](Excel.png) Button.

### 3.16 Protocol Information

This page shows all information regarding the measurement protocol used to create the current test run data. The information is shown in several parts:

#### General information

This section shows the serial number of the reader used, the version of the control software and the firmware along with the user name.

#### Audit trail / Signature

The audit trail information of the test run is displayed here. It displays any modification or manipulation of the test run. If the test run is signed, the signature details are also displayed here.

3.18 Measurement Notifications
This page appears, if warnings or other important events arose during the measurement of the test run.

The page shows for each event the corresponding message line.

3.19 Color Settings
If the Color View Mode in the Microplate View is active or if the Well Scanning window is open for well scan test runs, the Color Settings window will then be available.

Press the button behind the Colors check box or the Color Mode Settings button in the Working Area group on the View tab to open the Color Settings dialog box. On the Well Scanning dialog box, press the Colors ( ) button to open the dialog box:

Each displayed data row in the microplate view can have its own color settings. Select the data row at the top of the dialog for which the color mode settings should be changed.

If the Color View Mode is active the settings selected will affect the way the data in the Microplate View will be shown.

To change the display mode, select one of the three color modes available.

3.19.1 Two Colors (Good, Bad)
To show a good / bad (pass / fail) decision, you should choose this option to display a color for all values under a certain threshold and to display a different color for all values above the selected threshold. It is possible to select the two colors in use and to change the threshold value.

3.19.2 Three Colors (Range)

This uses the same concept as 'Two colors', but here you can also define a range 'in-between' to be displayed in a third color.

3.19.3 Color Gradient

The measurement values will be displayed using different shades of colors or gray levels. The start and end color of the scale can be defined by the user, it is also possible to use colors from the rainbow spectrum. The range of values displayed can be defined allowing the user to select the start and the end values to enlarge the range of the color gradient used.

The auto scaling function when applied will set the start and the end values of the range automatically to the minimum and maximum measurement values at the selected wavelength for the whole plate (based on the selected data row).

3.20 Printing Your Data
To create a printed report of the measured and calculated data open the Define Print Pages window. Click „Print Define“ in the Test Run group on the Home tab of the Ribbon or open the Print menu in the File menu and click Define Print to open the window.

The window is separated in four sections described below: Printer Settings, Available Print Object List, Selected Print Object List and Small Preview.

Press the Print button to generate and print the report.

The Header / Footer button opens a window to define the header and footer to be printed on each page as described later in this chapter.

Press the Print Settings... button to change common print settings (chapter 3.20.5: Print Settings).

Click Page Setup to define page margins (see Define Page Margins below).

To print only certain pages, use the Print pages entry field. Type the page numbers and/or page ranges separated by comma. For
example, type 1, 3-5, 7 to print the pages 1, 3, 4, 5 and 7. Leave the field empty to print all pages!

Note: There is a limit of maximum 200 print pages.

Printer Settings

In the Printer Settings section of the window select the printer and the print orientation (landscape or portrait). To change further settings of the printer press the Printer Setup... button to open the systems Print Setup window. The print destination can also be a PDF file or an HTML file. The name of the Print button changes to Saves as PDF and Save as HTML respectively if PDF or HTML is selected as print destination. In this case you will be asked to enter a file name after pressing the button. If available, MARS opens the Acrobat Reader application with the generated PDF file if Save as PDF was pressed: If Save as HTML was pressed, MARS opens the default HTML-Viewer (e.g. Microsoft Internet Explorer) with the generated HTML pages.

Available Print Objects

The list Available Print Objects holds all present printable objects (such as tables, charts, settings...). By double clicking on an object or by pressing the small arrow button (▶), you can add the object to the Selected Print Object list.

If an object is shown in blue, it is at least added once to the Selected Print Objects. If an object cannot be added it is shown in gray. This can be if its maximum number of selection is reached or if the object was not initialized yet (to initialize an object, open the appropriate page in MARS).

If the microplate view displays more than one row, a check box below the list is shown. Check this control to print each data row in its own microplate table:

| Print each data row in a separate microplate table (print result) |
|---------------|----------------|----------------|-------------|----------------|----------------|
| 6 | 1 | 2 | 3 | 4 | 5 | 6 |
| 3.5 | 1.229 | 0.324 | 1.719 | 0.315 | 0.306 |         |
| 1.371 | 0.423 | 0.298 | 0.391 | 2.157 | 0.891 |         |
| 1.040 | 0.303 | 0.301 | 0.459 | 1.786 | 1.599 |         |
| 3.5 | 1.065 | 0.341 | 2.152 | 0.313 | 0.361 |         |
| 1 | 2 | 3 | 4 | 5 | 6 |
| 3.194 | 0.553 | 0.109 | 0.138 | 0.119 | 0.102 |         |
| 0.210 | 0.115 | 0.080 | 0.228 | 0.958 | 0.184 |         |
| 2.526 | 0.406 | 0.406 | 0.078 | 0.396 | 0.129 |         |

Not checked

Selected Print Objects

The Selected Print Objects list shows the objects to be printed. The order of the objects in the list defines the sequence in the report. The position of an object in the list can be changed with the ▲ and ▼ buttons at the right side of the list. You can also select the object in the list and move it with the mouse to its new position.

To remove an object, press the ▶ button.

Page breaks are added automatically, if needed. To enforce a page break between two objects, select the object before the desired page break and press the ▼ button.

Print Comments

If you add a Comment object from the available print objects to the report, a dialog opens where the comment can be entered and formatted:

With the Alignment and Font controls, you can define the format of the comment. In the preview area at the bottom of the dialog, you can see the resulting comment.

To insert predefined values like date, time, test run information and many more at the cursor position, use the drop down menu Insert field at cursor pos. The available fields is a subset of the fields, available for header and footer (see Available fields and their meanings table later in this chapter). After selecting an entry from the list, press the OK button to insert the field into the comment.

With the Add calculated value at cursor position... button any value available in MARS can be added to the comment at the cursor position. See chapter 4.2.1: Define and Use Variables to read more about calculated values and system variables.

If the comment contains such a value, you can see detailed information of this variable value, if you move with the mouse pointer over the place holder of this variable.

You can change the way the number of such a value is printed (number of digits, scientific format...). Select the variable in the Number format for variables drop down list and define the settings in the appearing dialog.

To change a comment in the report, double click on the comment object in the selected print object list.

3.20.1 Preview

At the right side of the window, a preview window is shown. The preview will be updated each time the report will be changed. You can resize the window to enlarge the preview section. To open a separate preview window press the Preview button.

Use the ▲ and ▼ buttons or the slider control on the right side of the preview to change the displayed print page.

Click ▲ above the preview to see the page margins in the preview window as dashed lines. Click it again to hide the lines.

Use the Preview Mode control to define the
preview quality between high speed (best for many print pages) or high quality (best for real WYSIWYG = what you see is what you get).

Change the size of charts in the print output:
You can change the size of charts like the signal curve, the standard curve, the spectrum curve or the enzyme kinetic fit curve in the print output.

After moving the mouse over the chart in the small preview area, a blue dashed line is shown around the chart. Click on the border of the line with the left mouse button, hold the mouse button and move the mouse to change the chart size.

The window comes with a section to define the header and a section to define the footer. Both, defining the header and the footer work the same way.

A header or footer exists of one or more lines/rows. Each row is separated in three parts (section cells): A left part, a middle part and a right part. The text alignment depends on the part of the row in which the text was entered:

<table>
<thead>
<tr>
<th>Section Cell position</th>
<th>Text Alignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Left</td>
<td>Left</td>
</tr>
<tr>
<td>Middle</td>
<td>Center</td>
</tr>
<tr>
<td>Right</td>
<td>Right</td>
</tr>
</tbody>
</table>

You can add new rows with the Add Row button and you can remove a row with the delete button at the right side of the concerned row.

You can put a frame or borders at the sides of the header or the footer with the check box controls:

The border lines will be printed in black.

You can disable the complete header or footer by checking the Disable Header / Disable Footer check box control.

Enter header or footer text:

To add a row to the header or footer, press the Add Row button. Move the mouse over the part of the row, where the position of entered text should be until you see a framed section. Click on this section and a blinking edit cursor is show. Now you can enter the desired text.

Note: If the section contains a graphic, you will see no frame. If you click on the graphic a small delete button appears on the top right corner of the graphic. You can delete the graphic with this button and enter the text afterwards. In one section cell text and graphic content cannot be combined.

Change the font style of the entered text in one section cell:
Select the concerned section cell like described in Enter header or footer text above and change the font settings with the font settings controls at the top of the window.

The font settings can be defined for each section cell separately.

Use fields in header or footer rows:

Each section cell of a header or footer row can contain text combined with fields. Use the fields to enter page numbers, date, time or test run information and many more to the header or footer.

To insert a field into a cell, select the desired field in the drop down menu Insert field and select the cell like described in Enter header footer text above. Set the curser in the cell do the desired
position of the field and press the OK button on the right side of the Insert field drop down menu.

Unlike normal text, fields are displayed in gray and enclosed in # if a section cell is selected. To remove a field, click on the field when its section cell is selected. A small delete button appears on the top right corner of the field. Press the button to remove the field.

If a section cell with fields is not selected, MARS replaces the field name with the field value if possible (e.g. instead of #NoPages# #5 is shown if the report has 5 pages).

A selected section cell with fields:

```
Reader: #Reader# User: #User# ( #User path# )
```

The same section cell but not selected:

```
Reader: OMEGA User: USER (c:\program files\bmgr\omega\user\Data\)
```

Available fields and their meanings:

<table>
<thead>
<tr>
<th>Field</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Page number (#PageNo#)</td>
<td>Current Page Number</td>
</tr>
<tr>
<td>Number of total pages (#NoPages#)</td>
<td>Total number of pages the report created.</td>
</tr>
<tr>
<td>Title of the page (#PageTitle#)</td>
<td>The page title is created automatically, depending on the objects on the page (e.g. if the page contains the microplate and the table view, the page title is Microplate View / Table View)</td>
</tr>
<tr>
<td>Current date (#Date#)</td>
<td>The date when the report was created.</td>
</tr>
<tr>
<td>Current time (#Time#)</td>
<td>The time when the report was created.</td>
</tr>
<tr>
<td>Used reader series (#Reader#)</td>
<td>The reader series/family which created the measurement data (e.g. Omega, PHERAstar)</td>
</tr>
<tr>
<td>Used reader type (#ReaderType#)</td>
<td>The type of the reader which created the measurement data (e.g. POLARStar Omega, PHERAstar FS).</td>
</tr>
<tr>
<td>BMG User (#User#)</td>
<td>The BMG User.</td>
</tr>
<tr>
<td>BMG User directory (#User path#)</td>
<td>The path where the measurement data are stored.</td>
</tr>
<tr>
<td>Test Run number (#TrNo#)</td>
<td>The number of the test run in the test run data base.</td>
</tr>
<tr>
<td>Test Run name (#TrName#)</td>
<td>The name of the test run.</td>

<tr>
<td>Test Run ID2 (#ID2#)</td>
<td>The second test run id.</td>
</tr>
<tr>
<td>Test Run ID3 (#ID3#)</td>
<td>The third test run id.</td>
</tr>
<tr>
<td>Test Run Measurement Date (#TRDate#)</td>
<td>The date when the test run was measured.</td>
</tr>
<tr>
<td>Test Run Measurement Time (#TRTime#)</td>
<td>The time when the test run was measured.</td>
</tr>
<tr>
<td>Test Run Measurement Method (#TRMethod#)</td>
<td>Used test method of the test run.</td>
</tr>
<tr>
<td>Print 'signed' if the Test Run is signed (#IsSigned#)</td>
<td>Prints the text signed if the test runs is signed. If not, nothing is printed.</td>
</tr>
<tr>
<td>Print 'manipulated' if the Test Run is manipulated #IsManipulated#</td>
<td>Prints the text manipulated if the test run is manipulated. If not, nothing is printed.</td>
</tr>
<tr>
<td>Name of the application (MARS) (#ApplicationName#)</td>
<td>Prints MARS.</td>
</tr>
<tr>
<td>Program Version (#Version#)</td>
<td>Version number of the application.</td>
</tr>
<tr>
<td>Reader Company Name (#Company#)</td>
<td>Name of the reader company (BMG LABTECH)</td>
</tr>
</tbody>
</table>

Use graphics in header or footer rows:

A section cell can also contain a graphic instead of text. To insert a graphic into a section cell, select the cell (see Enter Header or Footer text above) and press the Insert Graphic button at the top of the window. A file dialog opens. Select a valid graphic file and press the Open button. The graphic will be inserted in the section cell. If the cell contains text or fields, they will be deleted.

To remove an inserted graphic, select the section cell; click on the graphic and press the appearing delete button on the top right corner of the graphic. Inserting a field in a section cell with a graphic will also replace the graphic by the field.

Create default Header and Footer

Press the Create Default Header and Footer button to overwrite the current header and footer with default ones. The default header and footer can be changed afterwards - this will not change the stored defaults (i.e. you can press the default button again to cancel the changes).

Export and Import Header and Footer

The current header and footer can be exported to store it in a file. Thus you can create different header/footer settings. These settings can be imported again and will overwrite the current header/footer settings.

To export the current settings press the Export Header and Footer button. An Export Dialog opens. Select the desired drive and folder and enter a file name (the extension is created automatically and must be MHF so that it can be imported again). Press the Save button to create and save the file with the header and footer settings.

To import a saved setting file, press the Import Header and Footer button. An Import Dialog opens. Select the *.MHF file containing the desired header/footer settings and press the Import button.

3.20.4 Quick Print Function

If you want to print data directly without open the Define Print window, you can use the Quick Print function in MARS. Press „Quick Print“ to start the printing of the data. Quick print uses the current defined print settings of the opened test run. If you have never defined or changed the print settings for this test run, default settings are used. With the default print settings always the currently displayed data page will be printed out (i.e. if the table view page is displayed, the table view page will be printed out).

3.20.5 Print Settings

The Print Settings window lets you change basic settings for printing. Click Printing in the Settings group on the Formats and Settings tab of the ribbon to open the window or press the Print Settings... button on the Define Print Pages window or open the MARS options menu and select the Print section.

**Print options**

| Print Microplates from 24 wells up to 384 wells in | The microplate view can be divided in more than one table, if the size of the plate is bigger than 12 wells. For plate sizes between 24 wells up to 284 wells, use this drop down menu to decide if the |
### 3.21 Export Data

In the next two sections it is explains how to create a single and quick data export into a text file or to excel either from the microplate or from the table view page. If you want to define a complete excel report for a single test run, read the last section (3.21.3) in this chapter.

#### 3.21.1 Export Displayed Data

**Export to Excel**

Data can be exported into Excel from the microplate view, table view and the protocol information by clicking on the Excel button shown on the upper left side of the page.

**Note:** If Microsoft Excel is not installed on the PC, the excel export is not available and the appropriate controls and buttons are disabled.

Each export sheet created shows at the top of the page the detailed information of the test run as in the upper section of the evaluation software. If you don't want to export the information or if you want to have this information at the end of the data, open the Excel Settings dialog box.

1. Click **Excel Export** in the **Settings** group on the **Formats and Settings** tab or open the MARS options menu and select the **Excel Export** section.
2. Select the desired behavior in the **Common Excel Export Settings** section:

   ![Common Excel export settings](image)

   If more than one end node or calculation in the navigation tree is selected in the microplate view, each item will be displayed in a separate table within the Excel sheet.

If well scanning data are displayed in the microplate view, a scan matrix with the measured values of each well will be exported to excel.

If the exported test run has more than one cycle/interval, you will be asked whether you want to export only the current cycle/interval or all cycles/intervals. If you decided to export all cycles/intervals, there are two ways the data for each cycle/interval will appear in Excel:

1. For each cycle/interval an Excel sheet will be created. The sheet name is a combination of the cycle/interval number and time value of the appropriate cycle/interval.
2. All cycles/intervals are shown in the same Excel sheet. The data group for each cycle is exported one below the other. A data group consists of one or more tables in the microplate format (a table for each selected data node). Each cycle/interval data group has a header containing the cycle/interval number and the appropriate cycle/interval time value.

To define, which export way should be used, open the Excel Settings dialog box:

1. Click **Excel Export** in the **Settings** group on the **Formats and Settings** tab or open the MARS options menu and select the **Excel Export** section.
2. Select the desired export way on the **Microplate View Export Settings** group:

   ![Microplate View export settings](image)

   If the test run generates more than 250 columns in the table view page, the data will be distributed on different sheets if the used Excel version limits the number of columns. Alternatively you can transpose the table before exporting it (rows and columns will be swapped), if you select the option **Transpose Table**.

**Export to a Text File**

Data displayed in the table view, in the microplate view or in the protocol information can be exported to a text file by clicking the button on the top of the according page. The generated file is stored in the comma separated value format. That means, each row of the table represents a row in the text file and the column values of each row are separated by a separator.
character. The destination directory, the file name, the preferred file extension (CSV, TXT or user defined) and the separator can be defined with the File Export Settings window.

The file can be created including the test run information header and available fit result tables or without this information.

The file name can be generated automatically \( \text{[Trn} + \{\text{Unique Test Run Number}\} + \{\text{[Selected Extension]}\} \) or defined by the user.

The generated files can be opened with any text editor or with excel. If the file extension is CSV and the separator is ’,’ for English systems or ’;’ for e.g. German system, Excel recognizes the file as data file and separates the columns into excel columns.

See an example of a CSV file taken from the table view including the header below:

```
user: user\nmicroplate: Microplate 1\ndata: day 28\nwell: A1\nsample: [s1]\ncalculation: \( \text{[Trn} + \{\text{Unique Test Run Number}\} + \{\text{[Selected Extension]}\} \)
```

### 3.2.1.2 Exporting Fit Results

If the data exported from the microplate or table view contain the result of a standard fit calculation or an enzyme kinetic calculation, an additional sheet in Excel will be created with the result parameter of the standard fit calculation.

To export the result parameters of all performed standard fit calculations or enzyme kinetic calculations, open the fit result window on the corresponding chart and press the \( \text{[N]} \) button.

### 3.2.1.3 Define an Excel Report

If you want to export not only a single data sheet, you can combine up to all available data pages in one excel report. Press the Excel Report button in the Test Runs group on the Home tab of the Ribbon to define the report:

![Excel Report Settings](image)

Define the data to export and the special settings for each exported page. The entered report configuration is valid for the opened test run and will be saved together with the test run settings.

The available settings are the same as for the single page export described in the two sections above. In addition, the option Use one workbook for each page allows defining, if all exported data should be copied in one excel workbook, or if a new excel workbook should be created for each exported data page.

### 3.2.2 Well Scanning Data

If the test run contains well scanning data, an additional view button \( \text{[N]} \) in the Microplate View will become visible. Pressing this button will show an overview of the scanned wells. The values are mapped to colors defined with the color settings window for well scanning data.

If more than one wavelength was measured (dual emission or multi-chromatic test runs) you must choose which wavelength to view using the drop down menu found above the microplate grid.

You can double click on a well to see a zoomed view of the measurement values along with additional information. In this detailed view it is possible to change the scan diameter used for the well calculations of this well, individual thresholds for this well, exclude single scan points and define areas inside the well.

With the button \( \text{Thresholds...} \) you can define thresholds to exclude scan points valid for all wells (read section Using thresholds to exclude scan points in this chapter).

With the \( \text{Diameter...} \) button you can set a new used well diameter for all wells:

![Well Scanning Data](image)

Use the Overwrite individual threshold settings of single wells check box to overwrite the individual well diameter settings. If this control is not checked, individual well diameter settings (if defined) will be preserved.

The used scan diameter describes the diameter of a circle (for a round well shape) or of a square (for a square well) that defines the area within the measured data points are used for further calculation.

Changing the diameter size allows users to reduce this area to exclude potential inaccurate readings from the edge of the well.

Use the Area detection... button to detect areas inside the well. Read more about area detection in the section Well Scan Area detection at the end of this chapter.

Clicking on the Excel button \( \text{[N]} \) will export a scan matrix with the measured values of each well to excel.

### 3.2.2.1 Detailed View of Well Scanning Data for a Selected Well

Double clicking on the well in the Microplate View when the Well Scanning View Mode is active, will open the detail window for this well.
In this window a zoomed view of the selected well will be shown along with some other additional information. When moving the mouse cursor over a scan point, a hint will appear showing the measurement value of the point. The picture contains three circles (for round wells) or squares (for square wells) with the following descriptions:

**The fat black line:** Shows the scan diameter used for calculations on the well. All scan points that fall outside of this line will not be used and are marked to indicate them as not in use.

**The fat gray line:** Shows the physical scan diameter. This is the diameter used by the reader as a limit when the well is scanned. Only scan points of the defined matrix whose centers lie inside this area are measured. The scan diameter is selected in the protocol settings of a test run in the reader control software.

**The thin black line:** Shows the border of the well as defined in the microplate database.

When the mouse cursor is moved over one of these border lines, a hint will be displayed showing the identifier and size of the border.

**Information and controls on the right side of the Window.**

**Calculated Values:**
It contains statistic values for this well like average, standard deviation, %CV, minimum, maximum, sum and num of used scan points.

**View Settings**
To display the values of each measured scan point, select *Show values*. The image will change and the values for each scan point will be shown instead of a colored square. It is recommended to maximize the window when using this function so that the font can be displayed in a readable size.

To change back to viewing the data in color mode select *Show colors*.

Press the *Colors* item to change the selected color mode and its settings (see chapter 3.19: Color Settings). The color legend shows the color gradient between the minimum value (Min:) and the maximum value (Max:) of a selected well. To adjust the color settings, you can use the color range selector on the right side of the chart.

To get a three dimension view of the well, select *Show 3D chart*.

The section *Threshold and Diameter - Area/Cell Selection* on the window is then replaced by the section *Chart Settings* to change the zoom value, the rotation and the elevation of the chart.

**Threshold and Diameter - Area/Cell Selection**
The *Threshold and Diameter* tab offers controls to exclude single scan points from this well for further calculations.

**Exclude Single Points**

Single scan points can be excluded from the selected well by clicking on them. Clicking on an excluded scan point will reactivate the point within the calculations for the well. Excluded (unused) scan points have a checked pattern on them.

**Note:** Scan points that have been excluded using the Scan Diameter Used function will not be reactivated by clicking on them. To reintroduce these points the scan diameter must first be increased.

Pressing the *Reset* button will change back the state of each scan point to ‘used’, if its center lies inside the area defined by the Scan Diameter in use.

To define thresholds for excluding scan points, press the *Define Thresholds* button. For more details on how to use thresholds to exclude scan points see Using thresholds to exclude scan points below.

**Change Scan Diameter**

The slider control is used to change the diameter. Use the mouse to move the slider and change the diameter. Data points falling outside of the selected area will be displayed in a gray pattern indicating, that these points will not be used for calculating the result value of the well scanned.

Alternatively the border in the image can be moved by using the mouse to change the diameter. Move the mouse over the fat black line in the image until a hint showing *diameter used xxx mm* appears and the mouse cursor changes to two arrows. Press
the mouse button and the color of the border will change to blue, it can then be moved to the desired size before releasing the mouse button.

The Reset button sets the diameter back to the scan diameter value.

To export the measured values to Excel press the button. A matrix of the scanning matrix dimension will be generated in Excel and filled with the values of all the scan points measured.

To print the window, press the Print button . A window to define the print destination (printer, pdf or html file,...) print orientation, page margins and header or footer contents will be opened (see chapter 3.20: Printing Your Data)

Click the save button to save the well scan detail as a bitmap file or to the clipboard.

Using thresholds to exclude scan points

Beside reducing the used scan diameter and clicking on single scan points, there is a third way to exclude scan points from further calculation.

You can define thresholds to exclude single scan points with the window that is show after pressing the Define Thresholds button:

There can be four threshold values which can be combined: One to exclude values below a certain number, one to exclude scan points above a certain number and two to exclude scan points between these numbers.

To use a certain threshold, activate the according control by checking its check box.

If the Global Well Scan Thresholds dialog is used, an additional check box control at the top of the dialog is available: Overwrite individual threshold settings of single wells. If this check box is checked, the global threshold settings will overwrite the individual settings. If this control is not checked, individual threshold settings (if defined) will be preserved.

Well Scan Area detection

The area detection is used to find and highlight areas inside the well. There can be one or more areas inside a well. This can be a group of cells located on different positions inside the well.

There are three ways available to find and define areas:

1. Select the a scan point inside the area

Select the first control (Click in the image on the center of a new area and adjust the area with the slider)

Click on a significant scan point inside the area you want to define. The area will then be selected automatically, based on the settings of the Area size slider.

The defined area will appear below the controls. You can use the appearing slider on the right side of the area control to adjust the size of the area:

2. Manually define the border of the area

Select the second control (Select the new area in the image by surrounding it with the mouse)

Use the mouse to surround the desired area with the mouse inside the scan image by pressing the left mouse button. Keep the mouse button pressed as long as you define the area border. After releasing the mouse button, the area will be defined according to the border you drew with the mouse.

Manually defined areas do not have a size slider. You can add or remove single scan points at the border of these areas with a right click on the scan point you want to add/remove.

3. Detect areas automatically

You can let MARS try to detect the areas inside the well automatically. The result of the automatic detection is depending of the significance of the Signal and how good the areas are divided from each other. Please check the detected areas after the auto-detection procedure to verify the result. You can adjust the detected areas in their size and you can remove single areas by clicking on the red cross on the right side of the area name (area1, area2...). You can also add further areas to the detected ones by using one of the first two methods.

To start the automatic detection, click on the Auto detect areas button. The Auto Detect Areas Settings box opens:
The size and the position of the window can also be changed and is stored during the whole program session.

Click the button to change the layout of the test run (see Changing Layout).

### 3.24 Settings

General Settings for MARS, Excel- or file export, number formats or spectrum display can be found in the options dialog:

- Open register File
- Select Item Options

A second way is to open the register Formats and Settings and select the option you want to see in the settings group:

#### 3.24.1 MARS Settings

The MARS settings dialog box lets you change general settings. Click General in the Settings group on the Formats and Settings tab to open the window or open the MARS options menu and select the General section.

Click OK to apply the changes and close the window.

### Navigation Tree and Test Run options

| Auto select only last created Nodes | If this control is checked (default), the behavior of the navigation tree is like this: If a new node or group of nodes is added, previous selections are deselected and only the new node(s) is selected in the display. If the box is not checked, the previous selections will remain active in the display as long as there are free selectable rows left (see Maximum number of selectable rows below). New nodes will be selected automatically. If no more rows/colors are left for allocation, the previous selections will be deactivated to make room as new nodes are added. |
| Maximum number of selectable rows | Enter the number of rows that can be selected in the navigation tree if the microplate view or the table view is visible. The minimum and default is 5 and the maximum is 20. |
| Number of entries in last opened test run list | Enter the number of entries, shown in the Recent list in the File menu. The minimum is 0, default and maximum is 10. |
| Automatically save test run settings | Saves the test run settings automatically when closing the test run. |

Define the default areas size and the sensitivity for the detection. You can repeat the detection with different settings, to get the settings for the best result. The best settings can be individual for each test run. A repeat of the auto-detection will delete all already detected areas.

If the expected areas have a higher signal than the background, choose the first mode (Signal/Value of Areas is higher than background), if it is lower, choose the second one. If it is not clear or if you want MARS to find out choose the last mode (Auto detect areas and background). Press Apply to start the detection and validate the result.

If the area detection was started for all wells, the box has an additional button Remove all areas to remove already detected areas for all wells.

### 3.23 View Microplate Layout

The microplate layout window shows the layout data of the plate. This is a useful tool to get a quick view on the layout even if the microplate view is not the active page.

Click the layout button in the Display group of the Home ribbon to open the window.

Data can be selected to be viewed using the controls above the grid. Some controls only appear when the according data exists in the layout, i.e. if the test run has no injections, the volume group controls will not be visible.

The grid can be zoomed in and zoomed out using the buttons shown. To reset to a view of the whole plate use the whole plate button .

If the reading order of the wells was recorded by the reader, you can display the reading order with the control Show Reading Order. Click the Animate button to see a visual animation of the reading order.
Menu Bar and User Interface options

<table>
<thead>
<tr>
<th>Color scheme</th>
<th>Select the desired color scheme (blue, silver, black)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Office Menu Style</td>
<td>Select the used menu style (Office2007, Office2010, Office2013, Office2016 or tablet style). Tablet style uses small menu icons.</td>
</tr>
<tr>
<td>Native Style</td>
<td>Display dialogs, windows and controls in the style, defined by the current window style.</td>
</tr>
</tbody>
</table>

Chart Comment Font

| Default font used for chart comments | Define the font, used for comments added to charts. To change the font click Change... and select the desired font in the Font dialog box. |

Plate Layout options

| Allow different dilution factors for replicates | In standard mode, each replicate gets automatically the same dilution factor. Set this control to enter different dilution factors for each replicate. You can change the dilution factor of wells within the change layout (chapter 6.1.3) procedure of MARS. |
| Allow different sample IDs for replicates | In standard mode, each replicate gets automatically the same sample ID. Set this control to enter different sample IDs for each replicate. You can change the sample ID of wells within the change layout (chapter 6.1.3) procedure of MARS. |

Value Display options

| Output text for invalid or not calculable values | Enter a text to be displayed if the value of a well is invalid, not available or not calculable. The default text is n.a. (not available). |
| Output text for injection/shake only cycles | For cycles with no measurement data (injection only or shake only cycles), define what to be displayed instead of the measurement value: -<default>: displays Inj. for injection only cycles, Shake for shake only cycles. -0: display always the value 0. -<empty>: display nothing -<injection volume>: for injection only cycles: display the injected volume. |
| Output text for not available chromatic values | This setting is only available if the used reader has a build in monochromator. Define the displayed text for a selected chromatic where no value is available (only possible if an excitation and emission scan was performed). |

Microplate View options

| Show hints of wells under mouse position | If selected, a hint will be displayed for the well under the mouse position. |
| Display selected curves in black (instead of row color) | Shows all selected kinetic or spectrum curves always in black (for higher contrast) instead of the color of the row selection. |

Fit Result Display options

| Display confidence interval parameters as default | The fit result window for standard fits will display the parameter values for the confidence interval beside the other fit result parameters when first opened. |

3.2.4.2 Excel Export Settings

The excel export settings window lets you change the settings for text file export of the MARS microplate view, table view or protocol settings. The window can be opened by clicking the File Export command in the Settings group of the Formats and Settings tab or open the MARS options menu and select the File Export section.

To open the window, select the Formats and Settings Tab on the Ribbon and press the Excel Export button on the Settings group or open the MARS options menu and select the Excel Export section.
The text file will be generated as Comma Separated Value (CSV) file, which means, each row of the table is a row in the file and the columns of each row are separated by a separator in the file. The file can be opened with any text editor (e.g. notepad) and, if the text file is stored with the extension CSV, it can also be opened with Excel.

**File content options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Add header and fit results to file</strong></td>
<td>Check this control if test run information and - if available standard fit results should be added to the file. The information will be stored above the table data in the file.</td>
</tr>
<tr>
<td><strong>Transpose Table</strong></td>
<td>This function is only valid for the MARS table view. For tables with many columns and only a view rows it can be useful to swap the columns with the rows before exporting the data. Check this control to transpose the rows with the columns of the table.</td>
</tr>
<tr>
<td><strong>Last cycle first</strong></td>
<td>This function is only valid for the MARS microplate view if the test run contains kinetic data. If selected, the export starts with the last cycle in the generated file instead of the first cycle.</td>
</tr>
</tbody>
</table>

**File Name and Location options**

| **Output directory for the created text files** | Enter the directory path, where the generated files should be stored. Use the button to open an explorer window to select the destination directory. The directory can also contain automatic text to sort the exported files. The same syntax like for the file name is used (except the automatic file name creation). |
| **File name** | Enter the name of the file without file extension or use the drop down list, to select one of the proposed file names. You can use either constant typed in text or automatically generated text (enclosed in < and >). You can combine constant and automatic text. See the description of the syntax for automatic file name creation below. Each new name, entered by the user will be added to the drop down list for further usage. To reset the list to its default entries, click **Reset List**. |
| **File Extension** | Select the extension of the file. You can choose either CSV (which is the usual ending for those kinds of files) or TXT (which indicates, that the file is an ASCII text file) or you can enter an extension you like. |
| **Separator** | Select or enter a separator. The separator separates the columns value of each row. The standard separators are: , and ;, depending on the operating system language (English, German, French...). |
| **If file exists** | Define the behavior what MARS should do, if there is already a file with the same name: rename old file by adding date/time: the existing file will be renamed by adding the current date and time to the file name. overwrite old files: the existing file will be overwritten (without prompting) append data (with separation line): the new export data will be appended to the file separated by a dashed line. append data (without separation line): the new export data will be appended to the file separated only by an empty line. |

**Automatic file name creation:**

The file name can be generated automatically, using the following options:

<table>
<thead>
<tr>
<th><strong>Pattern</strong></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;file name&gt;</td>
<td>MARS creates the filename automatically, combining the fix text Tn0 with the test run id. Example: Tn03.CSV (assuming the selected file extension is CSV).</td>
</tr>
<tr>
<td>&lt;test run name / protocol&gt; or &lt;test run name&gt;</td>
<td>Name of the test run (and the protocol the test run was created with)</td>
</tr>
<tr>
<td>&lt;method&gt;</td>
<td>Name of the measurement method, e.g. Fluorescence Intensity or Luminescence</td>
</tr>
<tr>
<td>&lt;ID1&gt; ... &lt;ID3&gt;</td>
<td>Plate ID1 ... Plate ID3</td>
</tr>
</tbody>
</table>

**File open with ... options**

**Note:** This setting is not used, if MARS is running in automatic mode or if the text files are generated from the manage test runs list. In these cases, the generated files are only saved at the defined location.

| **Open generated file with** | Check this control to open the generated file automatically. You can either select or enter a program to open the file or you can find the operating system the default program for the generated file. To define the program, enter the name or browse the directories after pressing the button to find the desired program. Select <default application> and the operating system opens the file with the program, linked to the defined file extension. If <open folder only> is selected, the windows explorer starts with the folder opened, where the generated file is stored. Each new application, selected or entered by the user will be added to the drop down list for further usage. To reset the list to its default entries, click **Reset List**. |

**Auto create csv report options**

**Note:** This setting is only used, if MARS is running in automatic mode or if the text files are generated from the manage test runs list.

| **Export table view** | If selected, the generated file contains the content of the MARS table view. |
| **Export microplate view** | If selected, the file contains the content of the MARS microplate view. |
| **Export all chromatics of well scan data:** | If the test run contains well scan data with more than one chromatic, only the first chromatic will be exported if this control is not checked. Check this control to export the well scan data for each chromatic. |
| **Export protocol settings** | If selected, the file contains the content of the protocol information page |
| **Export variables and calculated values** | If selected, variables and calculated values will be integrated into the export. Select the the type of variables you want to export (user defined variables, calculated values and fit result values). You can choose between the standard format where the name and the value will be exported using the selected separators, or the dedicated script module format, which can be used in the control software script language. |

**Spectrum Display Settings**

The Spectrum Display Settings window lets you change the settings for spectrum chart presentation. Click Spectrum Display in the Settings group on the Format and Settings tab of the Ribbon to open the window or open the MARS options menu and select the Spectrum Display section. The command button is only visible, if the used reader can have a spectrometer installed for absorbance measurements (like Omega, CLARIOstar, SPECTROstar Nano or PHERAstar FS) or if the reader has a monochromator (CLARIOstar).
Spectrum curve options

- **Show spectrum bar in the microplate view**: If checked, a small spectrum bar is displayed under the spectrum curve in each well used in the microplate view, if the spectrum view mode is active.
- **Show selected wavelength lines in corresponding color**: If checked, the wavelength lines viewed in the spectrum curve chart will be displayed in the color of their lambda value.
- **Show spectrum colors as background of the spectrum curve**: If checked, a light background, colored according to the lambda value of the X axis is displayed in the spectrum curve chart.
- **Intensity of background**: This sliding bar is enabled, when the spectrum color background above is checked. The intensity of the background can be changed using the slider.

### 3.24.5 Number Format Settings

The presentation of numerical data is based on general number format settings. These settings are defined with the **Number Format Settings** window. Click **Number Format Settings** in the **Number Format** group on the **Formats and Settings** tab of the Ribbon to open the window or open the MARS options menu and select the **Number Formats** section.

To change the presentation of certain number formats use the function described in chapter 3.24.6.

Press the **Reset all to Default** button to reset all changes to default settings.

#### Global time format options

<table>
<thead>
<tr>
<th>Use automatic display format</th>
<th>Select this mode to use the automatic time format function. Time values are displayed in one of the four ways shown in the table below:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum displayed time value</td>
<td>value displayed in</td>
</tr>
<tr>
<td>&lt; 2 seconds</td>
<td>ms (milliseconds)</td>
</tr>
<tr>
<td>&gt;= 2 seconds and &lt; 5 minutes</td>
<td>s (seconds)</td>
</tr>
<tr>
<td>&gt; 5 minutes and &lt; 5 hours</td>
<td>min (minutes) (e.g. 24 min 13 s)</td>
</tr>
<tr>
<td>&gt;=5 hours</td>
<td>h (hours)</td>
</tr>
</tbody>
</table>

You can change the default limits to switch between the different display formats: Click **Advanced Settings**... to open the **Advanced Kinetic Display Format Settings** dialog box and enter the desired values:

- **In seconds**, **In minutes**, **in hours**: Select this mode to display time values always in seconds or in minutes or in hours.
- **User defined format**: Select this mode if you want to define your own time display format. Use the drop down list to select one of the proposed formats or enter your own format. See the table below, how to define the format:
  - h hours. Only as many signs as needed are displayed.
  - hh hours. Minimum two signs are displayed (02 instead of 2).
  - m minutes. Only as many signs as needed are displayed.
  - mm minutes. Minimum two signs are displayed (02 instead of 2).
  - s seconds. Only as many signs as needed are displayed.
  - ss seconds. Minimum two signs are displayed (02 instead of 2).
  - z milliseconds. Only as many signs as needed are displayed.
  - zz milliseconds. Minimum two signs are displayed (02 instead of 2).
  
  **Note**: Using the formats s, z or ss,zzz is only useful for time values below one minute, because the seconds are only displayed up to 59. The same is for minutes above 59 (for e.g. m:ss,zzz).

- **Time Separator Character**: If the user define format is selected, you define the separator between time values (separator between hours, minutes, seconds and milliseconds) in this field.

**Note**: The time format settings are ignored for ALPHASCREEN, TRF and TRF advanced test runs!

#### Global number format options

- **Decimal Separator Format**: Select from the drop down menu the style of numbers used, either in the native format (defined by the operating system) or the English number format. The used style defines the decimal separator. The used separator is displayed behind the drop down menu.
- **Maximum number of digits before changing to scientific format**: Defines the maximum number of displayed digits. If the displayed value has more than the maximum number of displayed digits and **Switch to Scientific** (see below) is enabled for this value, the value is displayed in scientific format (e.g. maximum digits = 5, 0.00000123 is displayed as 1.23E-6).
- **Maximum precision before changing to scientific format**: Defines the maximum displayed value in floating point format. If the absolute displayed value is greater than the 10 * 1^n (n=maximum precision value) and **Switch to Scientific** (see below) is enabled for this value, the value is displayed in scientific format (e.g. n = 5, 2300000 is displayed as 2,3E6).
- **Use engineering notation of scientific format is used**: Check this box (default) if in scientific format the powers of ten should be multiples of three (e.g. 230000 is 0.23E6 instead of 2,3E5).
Data dependent number format options

MARS can display numerous types of data. For the different number types, the standard display settings can be defined separately. For each data type, the following settings can be defined:

<table>
<thead>
<tr>
<th>Format Representation</th>
<th>Use the drop down menu to define whether the data should be displayed in floating point style (like 1.243) or in scientific style (like 1.2E-3).</th>
</tr>
</thead>
<tbody>
<tr>
<td>Digits</td>
<td>Only enabled if floating point style is selected. Enter the maximum number of digits to be displayed for the number (the number will be rounded if necessary).</td>
</tr>
<tr>
<td>Fixed</td>
<td>Only enabled if floating point style is selected. If checked, the number will always be displayed with the entered number of digits. Missing digits are displayed as 0 (e.g. 1.2 is displayed as 1.200 if three digits are entered)</td>
</tr>
<tr>
<td>Switch to scientific</td>
<td>Only enabled if floating point style is selected. If checked, the presentation of the number will be switched to a scientific representation if the number exceeds the defined minimum or maximum limits for floating point representation. The limits are defined in the General Number Format Settings section above.</td>
</tr>
</tbody>
</table>

Press the Default button to reset the settings for this data type to default settings.

The last entry in the list Not specified Values is used for all numbers where none of the other entries in the list is valid.

3.24.6 Number Format Settings for Data Nodes and Chart Axes

The presentation of numerical data is based on general number format settings. These settings are defined with the Number Format Settings window. Click the Default Number Format Settings button in the Number Format group on the Formats and Settings tab to open the Number Format Settings dialog box.

In addition, the presentation of certain numerical data can be changed with the Change Format Settings dialog box.

These data can be:

1. The displayed data of each node in the navigation tree that refers to numerical data. For data nodes certain settings can also be changed directly with the controls in the Number Format group on the Formats and Settings tab:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Display data in floating point presentation</td>
<td><img src="image1.png" alt="Image" /></td>
</tr>
<tr>
<td>Display data in scientific presentation</td>
<td><img src="image2.png" alt="Image" /></td>
</tr>
<tr>
<td>Increase the number of maximum displayed decimal places</td>
<td><img src="image3.png" alt="Image" /></td>
</tr>
<tr>
<td>Reduce the number of maximum displayed decimal places</td>
<td><img src="image4.png" alt="Image" /></td>
</tr>
<tr>
<td>In Digits</td>
<td>If pressed (highlighted), the number of displayed digits is fix (see Always display digits below)</td>
</tr>
</tbody>
</table>

2. Axis labels of charts (each axis can be set individually).

To open the Change Format Settings dialog box for data nodes in the navigation tree, you have to select the concerned node in the tree and open the Change Format Settings... menu item in the popup menu of the navigation tree or click the dialog box launcher in the Number Format group on the Formats and Settings tab.

To change the number format settings of displayed axis labels, press the Change Settings button on the Axes settings tab to open the Change Format Settings window for this axis.

With the Reset to standard button the settings can be changed to the standard format settings defined in the Number Format Settings window.

The Standard Settings... button will open the Number Format Settings window.

To use the entered settings, press the Apply button.

Changeable Settings

The data can be displayed in a floating point representation or in a scientific representation:

Floating point representation

The floating point representation displays data in the normal format like 1.25 with a certain number of digits separated by the preset decimal separator.

<table>
<thead>
<tr>
<th>Digits</th>
<th>Enter the maximum number of digits to be displayed for the number (the number will be rounded if necessary).</th>
</tr>
</thead>
<tbody>
<tr>
<td>Always display digits</td>
<td>If checked, the number will always be displayed with the entered number of digits. Missing digits are displayed as 0. (e.g. 1.2 is displayed as 1.200 if three digits are entered)</td>
</tr>
<tr>
<td>Switch to scientific format...</td>
<td>If checked, the presentation of the number will be switched to a scientific representation if the number exceeds the defined minimum or maximum limits for floating point representation. The limits can be defined in the Number Format Settings window.</td>
</tr>
</tbody>
</table>

Scientific representation

The scientific representation displays data always in a format like 8.5E12 or 1.25E-9 where 8.5E12 means 8.5*10^12 and 1.25E-9 means 1.25*10^-9.

Time format representation

The time format representation displays data as time values. The format settings for time values can be set with the global time format options.
3.25 Outlier Detection

To identify outliers in a group of replicates in a defined and efficient manner, the outlier test based on Grubb is used. The error probability is fixed for 95%. To perform a statistical relevant test, a replicate group with at least six wells is needed. To start the outlier detection, select at least one replicate in the microplate view and open the popup menu with a right mouse click. Select the menu entry Remove Outliers.... You also can click on the Remove Outliers button on the Single Calculations group in the Calculations ribbon menu.

The outlier detection window opens:

Select input data: Select the input data for the outlier test. This can be the result of any calculation performed using replicates and output data in numbers.

Select Content: Select the content (= replicate group) you want to check for outliers. The values of each well will appear on the table below.

Select Wavelength: If the test run contains more than one wavelength data set, select the wavelength you want to check for outliers.

After the selection of input data, content and wavelength is completed, press the Apply selection button to start the outlier detection.

Beside the measurement value of the well some other values are shown to improve the valuation of the measurement: The absolute difference from the mean value, \( Grubbs \text{ Value}_1 \), and the difference between the 95% critical value and \( Grubbs \text{ Value}_1 \), expressed as absolute and percent value. \( Grubbs \text{ Value}_1 \) is calculated for each value with the following formula:

\[
Grubbs \text{ Value}_1 = \frac{|x - \bar{x}|}{s_d}
\]

This value is compared with a critical value depending on the number of wells and the error probability. If Grubb value is larger than the critical value, the corresponding well is marked with a red background. If you press the button 'Don't use', the status of this well will be changed to 'Not used' and will be excluded from the calculations in MARS. The well is grayed out on the microplate and table view page. You can redo this action by manually changing the status to 'Used'. The corresponding menu you get with a right click on the well on the microplate page. You can repeat this procedure until no outliers are detected anymore or the number of remaining replicates is less than six.

If no outliers can be detected in a given replicate group, a message 'No outliers detected' appears.

Note: You can access the outlier dialog also by clicking the right mouse button over standard markers on the Standard Curve page.

4 Perform Calculations

When opening a test run measurement in MARS for the first time, a default view will be displayed showing the measured raw data, the blank corrected data (if blanks were defined in the protocol settings) and the calculated averages of replicates (if replicates were defined in the protocol settings). See what happens, when you open a test run the first time in the chapter 2.5: Test Run Settings.

To further evaluate the data, MARS provides numerous calculation methods to choose from. Most calculations can be combined together and all intermediary results can be viewed.

Each calculation performed creates a new data node in the navigation tree. For calculations defined for data using more than one wavelength, the calculation will be performed for each wavelength (except for calculations where arithmetic operations between two wavelengths are used).

The calculation results can be viewed directly in either the microplate view or the table view, as a new data node is added to the navigation tree automatically after performing a calculation.

The performed calculation steps for a result data node are displayed in the detailed information window under the navigation tree. The steps are displayed as a hierarchical series with the last performed calculation shown at the top:

- **Standards calculations:**
  - Wavelength: 545 (1), 590 (No. 2A)
  - Linear regression fit
  - Based on:
    - Sum of Range 1
    - Average
    - Blank corrected
    - Raw Data

The top lines describe the last performed calculation for this node.

The Based on list shows all calculations performed successively starting with the latest. The hierarchy shows which calculation was performed on the output data of the previous calculation. The last line is always the raw data node because all calculations are based on the measured data.

To perform a new calculation click Calculations in the Data Reduction group on the Home tab of the Ribbon or select the required calculation method directly by clicking the corresponding control in the Single Calculations group on the Calculations tab. The calculation window will then open. If selecting the desired calculation in the Single Calculations group, the page of the selected calculation method will open automatically in the calculation window.

If the test run measured has standards in the layout and you want to perform a standard calculation (curve fitting), in most cases it is possible to use the standard calculation wizard to get a quick and easy result. Read how to use the wizard in the chapter 4.21: Standard Calculation Wizard.
After selecting a number of wells in the microplate view, calculations can be performed using the statistic over selected wells option. This feature becomes available, after two or more used wells are selected in the microplate view. To perform the calculation select the menu item Statistic over selected wells...from the microplate view popup menu or by clicking Statistic over Selected Wells in the Common group of the Calculations tab.

For test runs containing kinetic data, it is important to define ranges before creating calculations using the kinetic data. Read how to handle and use ranges in the chapter 4.1: Ranges.

To change the parameters of a previously performed calculation, this can be done by opening the node pop up window, by clicking on the calculation using the right mouse key. You can then select the Change calculation option from the menu to change any parameter of the calculation except the input data.

If the parameters of a calculation are changed and there are further calculations whose input data are the output data of the changed calculation, the corresponding calculations will also be recalculated.

4.1 Ranges

Ranges are used for test runs containing kinetic data or a measured spectrum.

A range defines an extract of your kinetic or spectrum data. A range can include the complete measurement data down to a single cycle/interval/wavelength of a measurement.

A full range over the whole kinetic/spectra data is always available. In addition you can define ranges with any possible start and stop value.

It is possible to define more than one range, and ranges can overlap. See how to define and manage ranges in the section Define a Range.

When having defined a new range, a calculation can then be selected and the input data for that calculation method defined. See the chapters 4.8: Kinetic Calculations and 4.18: Spectrum Calculations, how to perform calculations based on a range.

It is possible to define more than one calculation on the same range (e.g. both the slope and the average may be needed from the same range).

Kinetic ranges are displayed in the signal curve chart and in the range window. Spectrum ranges are displayed in the spectrum curve chart and in the range window.

Each range gets its own number starting with one. If unused ranges are deleted (ranges used to perform existing calculations cannot be deleted), the ranges will then be renumbered to compensate for this.

For kinetic ranges, it is possible to define a baseline range. It defines the cycles/intervals for a baseline correction. The baseline range can be differentiated from the other ranges by its name (baseline ranges are called baseline #n0., normal ranges are called range #n0. #n0 is the number of the range) and by its color in the signal curve chart as it will appear red instead of blue.

4.1.1 Predefined Ranges

For each kinetic or spectrum test run a full range for the whole kinetic/spectrum measurement is always available. This range cannot be changed or deleted.

If the test run contains injections, additional kinetic ranges will be defined: Creating one range before the injection and one range after the injection (the injection cycle). These are ranges that can be changed and deleted.

4.1.2 Individual Ranges

For calculations based on ranges (like the Kinetic Calculations and the Spectrum Calculations) you can also define individual ranges. Individual ranges can have a start and/or stop value that is not predefined. This allows you to define ranges that can be different for each well. The last entry in the range selection box of the calculation definition page is always the individual range. If you select this range, a dialog to define the range settings opens:

Define the settings for the start and the stop index for the range:

| Index at minimum | Finds the index position of the minimum value in the selected range. Use the Offset control to enter an offset index to the resulting index. |
| Index at maximum | Finds the index position of the maximum value in the selected range. Use the Offset control to enter an offset index to the resulting index. |
| Index at threshold | Returns the index position when the value in the selected range reaches the entered threshold the first time. If the threshold is not reached, the last index will be returned. Use the Offset control to enter an offset index to the resulting index. |
| Index from variable | The index is defined by the selected variable. Read more about variables in chapter 4.2.1: Define and Use Variables. Use the Offset control to enter an offset index to the resulting index. |
| First index | Returns the first index of the measurement (= 1). In combination with the offset value, you can define any fix start/stop index for the range. Use the Offset control to enter an offset index to the resulting index. |
| Last index | Returns the last index of the measurement. In combination with the offset value, you can define any fix start/stop index for the range. Use the Offset control to enter an offset index to the resulting index. |
| Index at Injection | Only for kinetic test runs with at least one injection defined: Returns the index of the selected injection cycle/interval. Use the Offset control to enter an offset index to the resulting index. |

4.1.3 Define a Range

To define a new range use the range functionality options shown on the signal curve chart and on the spectrum curve chart to add, move or resize a range or use the range menu.

You can open the window by clicking Ranges in the Data Reduction group on the Home tab of the Ribbon (the same can be done by clicking Define Ranges in the Common group of the Calculations tab).
The window shows up to two tabs, one for kinetic ranges (if the test run contains kinetic data) and one for spectrum ranges (if the test run is an absorbance spectrum measurement). On each page you see a list with all ranges and their start and stop cycles/intervals, respectively their start and stop wavelength.

To change the borders of a kinetic range, click in the cycle field you want to change and enter the new cycle value, or for a spectrum range, click in the wavelength field you want to change. These values can also be changed up or down, using the small spin control that appears on the right side of the field when you click on it.

It is possible to add a new range by clicking on the New Range button. The borders of the new range will cover from the first cycle/interval to the last, respectively from the first measured wavelength to the last. The border values can then be changed as described above.

To delete a range, select the range or ranges you wish to delete and press the Delete Range button.

With the Variable... button, you can use a variable or a value from another calculation to set the range start or stop cycle/wavelength. Read more about variables in chapter 4.2.1: Define and Use Variables.

Any changes made to a range that has had a calculation performed on it will result in calculation being recalculated according to the amended range.

4.2 Variables

4.2.1 Define and Use Variables

With MARS you can define variables to use them in calculations. During the calculation, the variable will be replaced by a certain value.

MARS knows three types of different variables:

- User defined variables
- Calculated values
- Calculated fit parameters

To use variables in calculations, the check box on the Calculations Ribbon menu in the Variables and Calculated Values group must be checked. You can find the same group with the button in the Templates Ribbon menu.

Note: Calculated values and calculated fit parameters can be used in the user definable formula, even if the flag is not checked. For all other calculations, the check box needs to be checked.

Parameters of a calculation that can be set by a variable are marked with an additional button (☆) on the left side of the parameter entry control. To assign a variable to the parameter, click on the button and select the desired variable. See section Select a Variable in this chapter for more details.

Note: The buttons are only visible, if the control is checked.

User defined variables

A user defined variable describes a placeholder for a value, entered by the user. This kind of variable is useful only together with templates. If a template was defined to perform always the same calculations, but only few parameters (e.g. an extinction coefficient or a threshold value) changes from test run to test run or from time to time, you can use a variable for this parameter. You can define a default value for the variable and you can decide if the variable has to be entered for each new test run or not.

If a variable needs to be entered and you assign the template to a test run, a dialog comes up and asks the user to enter the value for the variable. The appearing text can be defined together with the variable.

If the value of a variable changes only sometimes and not for each test run, you define a variable that does not need to be entered (see Create a new user defined variable below) and define a default value for this variable. To change the default value in the template, you can select the template in the Manage Templates window and click on the Edit Parameters button. Read the Manage Variables section below to find out how to change the default value of a variable.

See the flowchart below how variables are used together with templates:
Calculated Values
Calculated values can hold any value available for the test run. This can be either a measured value for a certain well or content, or a calculation result for a well or content. These kinds of variable allow you to define calculations between different processes. Read the section Add a new calculated value variable below, to see how to define such a variable.

Calculated fit parameters
Calculated fit parameters can hold parameter values of calculated standard fits for the current test run. These kinds of variable are available, as soon as standard calculations are done for this test run. They can be directly selected for further calculations (see section Select a Variable below).

4.2.2 Manage Variables
To see and change all defined variables or to define new variables, you need to open the variable manager. Click on the “Manage Variables and Values” button on the Calculations Ribbon menu (or on the Templates Ribbon menu) in the Variables and Calculated Values group to open the variable manager:

If the Activate variables in templates control is checked, you see two tabs (pages) on the window: One for the user definable variables (Variables tab) and one for the calculated values (Calculated Values tab). Otherwise you see only the Calculated Values tab.

Variables tab
The table shows all defined variables (if you open the table the first time for the test run, the list is empty). You can change the parameters [Display Text, Type, Minimum Value, Maximum Value, Default and Ask Always (= needs to be entered)] directly in the table or you can select a variable and click Change Variable to open a dialog with the parameter details. The dialog and the meaning of each parameter is explained in the Create a new user defined variable section below.

You can group user defined variables together so that the values for these variables (if they need to be entered) can be entered in one dialog:

Grouping variables
If you use more than one variable in a template that needs to be entered, there will come up a window for each variable. Sometimes the variables are used in the same calculation and are associated. In this case you maybe want to see them in one dialog. You can do this if you create a variable group with these variables.

You can have more than one variable group if necessary.

To group variables together in one group, select the variables in the table and click Combine in one Group. The number displayed in the group column shows the order of the variables in the dialog. You can change the order of the variable in a group with the and buttons. To remove a variable from a group, select the variable and click Remove from Group.

Click New Variable... to create a new user defined variable:

Create a new user defined variable
After you have clicked the New Variable... button on the Manage Variables window or on the Select Variable or Value window, the window to define a new variable comes up:

Enter the text that will be shown, when the parameter needs to be entered

Select the variable type

If checked, the parameter will be asked to be entered

Enter the text that will be shown for this variable in the first text field of the window. If you want to use user numbers in the text, where the decimal and/or thousand separator should be taken from the windows system settings, use #@ instead of the decimal separator and #* instead of the thousand separator: 1#*000#@25 instead of 1000.25.

The Value type of the variable can be:
1. Number (any floating point of integer value)
2. Boolean (any logical value like Yes/No, True/False...): for Boolean value the settings of the variable changes:

You can enter a display text for the true state and the false state. Boolean entry fields which can be used as parameters in templates are:
**True/False Overview table for logical entry fields in MARS**

<table>
<thead>
<tr>
<th>Calculation</th>
<th>Field Caption</th>
<th>True</th>
<th>False</th>
</tr>
</thead>
<tbody>
<tr>
<td>Content Based Correction</td>
<td>average or median</td>
<td>median</td>
<td>average</td>
</tr>
<tr>
<td>Baseline Correction</td>
<td>Mode</td>
<td>division</td>
<td>subtraction</td>
</tr>
<tr>
<td>Kinetic Calculations</td>
<td>Slope Direction</td>
<td>Rising</td>
<td>Falling</td>
</tr>
<tr>
<td>Spectrum Calculations</td>
<td>Slope Direction</td>
<td>Rising</td>
<td>Falling</td>
</tr>
<tr>
<td>Statistics</td>
<td>Absolute value only</td>
<td>absolute value</td>
<td>real value</td>
</tr>
</tbody>
</table>

**Text:** Can be used where text parameters are used.

**Enumeration:** You can select between these enumeration types:
- Slope Type (/hour, /min, /sec, /ms, /μs)
- Statistic calculation (Average, Standard deviation, …)
- Enzyme kinetic calculation (Michaelis-Menten, Lineweaver-Burk, …)
- Series type for plausibility checks
- Data calculations (minus, divided by, plus, multiplied by)
- Concentration calculations (Difference, Ratios, Percentage)

Press OK, to save the variable.

**Note:** The variable is part of the test run setting and will be saved together with the other settings. If you close the test run and open another one, you will no longer see the variable you just defined for the test run before.

**Calculated Values tab**

The table on the Calculated Values page shows the already added value variables for the current test run:

Calculated values are content (starting with a C in the name) or well values (starting with a W in the name) from any performed calculation of the current test run. The Data Source column shows the calculation which is the base for the data value.

If Groups are defined in the test run layout, the group column shows (important only for content values) the group of the variable. If the group column is empty, the average value over all groups is used.

If the test runs contains more than one wavelength, the Wavelength column shows the wavelength data base for the variable. If the wavelength column is empty, the value of the variables is calculated separately for each wavelength.

For kinetic test runs, the Interval column shows the selected interval for this variable (0 means, the value iterates over the intervals).

For content values, the content column shows the selected content, for well values the Well column shows the selected well.

If the value variable does not iterate over Groups, Wavelength, Intervals or Wells, the Value column shows the current value for this variable. If the Well column contains a x, the value of the variable iterates over each well.

To add a new calculated value variable to the list, press the Add Value... button.

**Add a new calculated value variable**

After you have clicked the Add Value... button on the Manage Variables window or on the Select Variable or Value window, the window to select a new calculated value comes up:

Use the controls to select any value of all available input data for the current test run:

Select the input data: Select the input data process for the value variable.

Wavelength If the selected input data process contains data of more than one wavelength, select the desired wavelength data. If you select the entry <calculate for each>, the value variable will be calculated for each wavelength.

Cycle/Interval If the selected input data process contains kinetic data, you can select a certain cycle/interval to define the value, or you can select <calculate for each> to iterate the value over the cycles.

Content If you select a content, the value will be calculated as the average of all wells of the selected content.

Group If the layout contains groups and Content is selected, you can select the group of the desired content or you can select <ignore groups> and the average of all wells of the selected content without considering the group information will be calculated or you can select <calculate for each> and the average of all wells of the selected content with the same group as the currently calculated well will be used.

Well Select a certain well for the value variable. If you want to iterate over all wells, select the x = iterate over all wells entry.

Value If the selected value variable defines a certain value (not iterating over the wavelength, cycle or well), the resulting value of the variable is displayed here.

Press OK, to add the calculated value variable to the selection list.

**Note:** The calculated value variable is part of the test run setting and will be saved together with the other settings. If you close the test run and open another one, you will no longer see the variable you just defined for the test run before.

**4.2.3 Select a Variable**

After you have defined one or more user defined variables or calculated values, you can use them in calculations.

Create the calculations you want and use the variable for the calculation parameters you want to have as a parameter in the template: Each parameter of a calculation that can be used as a parameter in the template has a small icon on the right side of the parameter (اظ):
If you click on this icon, a window with all available variables that matches for this parameter is shown:

The window shows two or three tables (the table with the user defined variables is only visible if the control is checked).

The green table shows all user defined variable. If no variable is defined you can create a new one with the New Variable... button (see Create a new user defined variable above).

The blue table shows all defined calculated values. To add more calculated values, press the Add Value... button (see Add a new calculated value variable above).

The orange table shows the available calculated fit parameters.

Select the variable you want to use and click OK.

The icon changes and the control to enter the parameter is disabled. To remove the assigned variable from the parameter, click the icon again:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cl</td>
<td>100</td>
</tr>
<tr>
<td>C2</td>
<td>0.704</td>
</tr>
</tbody>
</table>

4.3 Calculations

To perform a single calculation, select the calculation from the calculation window, define the properties of the calculation and perform the calculation by pressing the Apply or the Apply and Close button in the window.

Enter a name for the resulting calculation data in the entry field Result name: at the bottom of the window. The name will be used in the Navigation Tree and in the legend of the Microplate and Table View pages to identify the data.

Depending on the test run the following calculations can be performed:

Basic calculations:
- Blank corrections
- Negative control corrections
- Baseline corrections
- Statistics
- FP calculations
- TR-FRET calculations
- Kinetic calculations (Calculations based on ranges over cycles/intervals)
- Standard curve calculation (Curve fitting)
- Data calculations (Arithmetic operations between wavelength or output data of other calculations)
- Validations (Classifies the data in good / bad / unknowns...)
- Spectrum Calculations (Calculations based on wavelength ranges over a spectrum)
- Well Scan Statistics (If the test run contains well scan data)

Advanced calculations:
- Curve Smoothing (Curve smoothing for the signal curves and spectrum curves)
- Kinetic Curve Fitting (Curve fitting based on ranges over signal curves)
- Concentration calculations (Calculations based on known and calculated concentrations)
- Assay Quality (Z', signal to blank, signal to noise...)
- User Defined Formula (Formula generator based on well values)
- Enzyme Kinetic (Performs an enzyme kinetic calculation to calculate Km and Vmax)
- Curve Scaling (Converts a signal curve to a percentage presentation)
- Binding Kinetics (Binding kinetic fitting like kinetic rate equation)
- Curve Analysis (Area under Curve, Differentiation and Integration of curves)

The subdivision into basic and advanced calculations helps to simplify the window and allows you to find better the most often used calculations. You can change the division if you want to...
have some of the advanced calculations in the basic calculation section and vice versa. Just click the desired item in the menu and move it with the mouse to the desired section and position. The changed division will be saved - individually for each user - and restored after restart of the program.

To open or collapse a section click on the double arrows on the right side of the section caption.

**Special calculations:**

1. **Well statistics:**

Statistic over selected wells (Not found within the Define Calculations window, but if wells are selected in the microplate view, this calculation will be performed when the menu item Statistic over Selected Wells... in the microplate views popup menu or in the corresponding menu item under the calculations menu is selected).

Details of each single calculation are explained in the appropriate chapters of the calculation method.

To perform more than one calculation, just apply the defined calculation and change to the page of the next calculation you want to perform. The data of the newly created calculation will be immediately available to be used as input data for the next calculation.

To perform only one calculation at once, press the Apply and Close button to close the calculation window after the calculation was performed.

2. **Remove Outliers:**

If enough replicates are used, outliers can be removed automatically. How to find and remove outliers can be found in the chapter 3.25: Outlier Detection.

3. **Use Robust Statistics:**

Check the control Use Robust Statistics on the Common group in the Calculations ribbon menu to use robust statistics calculations for all performed calculations. Read more about robust statistics in the chapter 4.23: Robust Statistics.

**Using Variables in Calculations:**

If a parameter entry control of a calculation shows this element 📊, it can be set by a variable. Press the button 🔧 to open a new window with all available variables. An explanation of all different kind of variables and how to use them in calculations and templates can be found in chapter 4.2.1: Define and Use Variables.

The dialog with the available variables shows only variables that can be used for the appropriate parameter.

The Variable button is only visible, if variables for templates are activated. To activate variables for templates, check the **Activate variables in templates** button on the Calculations Ribbon menu in the Variables and Calculated Values group. You can find the same group with the button in the Templates Ribbon menu.

### 4.4 Corrections

The corrections page 📊 contains two groups. One page shows corrections made using the blank and negative controls, and the other for baseline corrections.

#### 4.4.1 Content Based Corrections

There are two groups of content based corrections: The blank corrections and the negative control corrections.

If the layout contains more than one blank or negative control you can define if the average or the median of all blanks/negative controls should be used for the correction with the radio control on the right side of the window.

**Input data:** Select the input data for the content based correction. This can be the raw data or the result of any calculation.

#### 4.4.2 Blank Corrections

**Blank Correction**

If there are blanks defined in the layout of the test run, it is then possible to perform a blank correction when you check the blank correction check box. If no blanks are available the check box will be disabled.

The blank correction calculates the average or the median of all available blanks and subtracts the value from the raw data.

**Blank Correction (Ignore Groups)**

If you have groups in addition with blanks, the normal blank correction would calculate the averages or the median of the blanks from each group and subtract the appropriate values from the corresponding groups.

If you want to calculate the average or the median of the blanks of all groups and subtract this value from all raw data, this can be done using: blank correction (ignore groups) option. This option is only made available if you have groups with blanks.

#### 4.4.3 Negative Control Corrections

**Negative Control Correction**

If there are negative controls defined in the layout of the test run, it is possible to perform a correction using the negative controls. Check the negative control correction check box. If no negative controls are available the check box will be disabled.

The negative control correction calculates the average or the median of all available negative controls and subtracts the value from the raw data.

**Negative Control Correction (Ignore Groups)**

If you have groups in addition to negative controls, the normal negative control correction will calculate the averages or the
median of the negative controls from each group and subtracts
the appropriate values from the corresponding groups.

If you want to calculate the average or the median of the
negative controls of all groups and subtract this value from all
raw data, this can be done using: negative control correction
(ignores groups) option. This option is only made available if you
have groups with negative controls.

4.4.4 Baseline Corrections

If a test run has kinetic data, this option is enabled to perform a
baseline correction.

The baseline correction will calculate the average of the values in
the baseline range and subtract or divide this value from all the
kinetic data of the selected input data.

Use the Correction Mode control to define if the values should
be subtracted or divided.

Input data: Select the input data for the baseline correction. This
can be the result of any calculation performed using
kinetic data or the raw data.

Define Baseline Range: Define the start and stop cycle/interval
of the baseline range. The borders of the baseline range can
be changed after applying the calculation. Open the signal
curve chart, and see that the baseline range is shown as a red
border range. Change the borders of the range as described in
the chapter 3.11.1: Range Functions in the Chart.

The calculation will be automatically updated.

4.5 Statistics

The statistics page is used to calculate statistics over
replicates or over layout groups.

If the selected input data has replicates and layout groups, use
the radio box controls Statistic over replicates / Statistic over
layout groups to define if the statistic is calculated based on
replicates or based on layout groups.

Input data: Select the input data for the statistic. This can be the
result of any calculation performed with output data in numbers.

Calculation method: Select the calculation method for the
statistic.

Available methods:

Average: Calculates the average (mean) of all replicates of the
same content (statistic over replicates) or of all wells of the same
layout group (statistic over layout groups)

Standard deviation: Calculates the standard deviation based on
samples (in this case replicates of the same content or wells of the
same group). The standard deviation is a measure of how
widely values are dispersed from the average value. The SD value
is calculated using the following formula:

\[ \text{SD} = \sqrt{\frac{\sum (x - \bar{x})^2}{n-1}} \]

Standard deviation n: Calculates the standard deviation based
on an entire population (in this case replicates of the same
content or wells of the same group). The SD n value is calculated
using the following formula:

\[ \text{SD} = \frac{\sum (x - \bar{x})^2}{n} \]

Note: The standard deviation the recommended standard
deviation method, as the measured data applies to an
entire population and not just the samples.

Standard error: Calculates the standard error of the mean based
on samples (in this case replicates of the same content or wells
of the same group). The standard error is calculated using the
following formula (standard deviation n divided by the square
root of the number of replicates):

\[ \text{SE} = \frac{\text{SD}}{\sqrt{n}} \]

%CV: Calculates the standard deviation of the replicates of the
same content (respectively wells of same group) divided by their
average and multiplies this number by 100 to express the result
as a percentage.

%CV n: Calculates the standard deviation n of the replicates of
the same content (respectively wells of same group) divided by
their average and multiplies this number by 100 to express the
result as a percentage.

If the method %CV or %CVn is selected a further control appears:
☐ Absolute values only (positive values only): Check this control if you want
to see only absolute (positive) %CV values.

Minimum: Finds the minimum value of the replicates of the
same content (respectively wells of same group).

Maximum: Finds the maximum value of the replicates of the
same content (respectively wells of same group).

Median: Finds the median value. The median is described as the
number separating the higher half of the replicates from the
lower half. The median is found by arranging all the values
to compare from lowest value to highest value and picking the
middle one. If there is an even number of values, the median is
not unique, so the mean of the two middle values is taken.

Sum: Calculates the sum of the values of all replicates of the
same content (respectively wells of same group).

No. of Values: Returns the number of replicates for one content-
type (respectively wells of same group).

4.6 FP and TR-FRET Calculations

These calculation methods are only available if the test run
is either a fluorescence polarization measurement (FP
calculations) or a TR FRET measurement (TR-FRET calculations)
using two measurement channels simultaneously (not available
on all readers!). Using these calculations, the two measurement
channels will be compared against each other. The available
calculation operations differ, depending on the measurement
methods:
4.6.1 FP Calculations

For fluorescence polarization measurements the polarization values are calculated automatically when the test run is opened. Using this calculation method, further calculations can be performed on the parallel and perpendicular raw data.

**Input data:** Select the input data for the calculation. This can be the result of any calculation which obtains the parallel and perpendicular channel data.

**Calculation:** Select the calculation you want to perform:

- **Available methods:**
  - **Polarization:** Calculates the polarization values in mP from the two measured channels (parallel and perpendicular).
  
    \[1000 \times (\text{parallel} - \text{perpendicular}) / (\text{parallel} + \text{perpendicular})\]

  - **Anisotropy:** Calculates the anisotropy values in mA from the two measured channels (parallel and perpendicular).
  
    \[1000 \times (\text{parallel} - \text{perpendicular}) / (\text{parallel} + 2 \times \text{perpendicular})\]

  - **Intensity:** Calculates the intensity values from the two measured channels (parallel and perpendicular).
  
    \[
    \text{parallel} + 2 \times \text{perpendicular}
    \]

4.6.2 TR-FRET Calculations

**Input data:** Select the input data for the calculation. This can be the result of any calculation which obtains data from at least two measured wavelengths.

**Ratio based on:** Select the first (numerator) and the second (denominator) wavelength for the ratio calculation.

**Calculations:** Select the calculation you want to perform:

- **Available methods:**
  - **Ratio:** Calculates the ratio between the two selected wavelengths/channels. Enter a multiplier for the ratio calculation in the field **Ratio multiplier**.

Delta F

Calculates the DeltaF value. If the layout contains a negative control, this content will be selected as negative control. If the layout has no negative control or if you want to perform the calculation based on a different content you can change the content if you select another entry in the drop down list negative control.

If the layout contains groups, you have to decide, how to handle groups with the Group Handling control:

- **Use selected content for all groups**
- **Calculate for each group**
- **Ignore groups**

The formula for DeltaF is shown in the screen shot above.

\[ \text{Ratio Signal} = \text{the ratio of the signal for which the DeltaF value is calculated} \]
\[ \text{and Ratio neg is the Ratio of the signal of selected negative control} \]
\[ \text{(Ratio means: [Value for wavelength 665nm] divided by [Value for wavelength 620nm]).} \]

4.7 Curve Smoothing

With the curve smoothing page one of two smooth calculations can be performed for the signal curves of kinetic test runs or the spectrum curves of a spectrum scan test run.

**Input data:** Select the input data for the calculation. This can be the raw data or the result of any calculation that obtains kinetic data or spectra data.

If the input data has both, kinetic and spectra data, you can select if the smoothing should be calculated based on the kinetic or based on the spectra curve with the radio control above the input data drop down list: Smooth kinetic curve / Smooth Spectrum curve

**Select range:** The input data for a curve smoothing calculation are always defined by the first cycle/interval and the last cycle/interval of a kinetic range or by the first wavelength and the last wavelength of a spectrum range. It is possible to have one or more ranges defined. The full range is always available and covers the total measurement. See the chapter 4.1: Ranges, how to define a range. All defined ranges are listed in the drop
down list with their start and stop cycle/interval or wavelength (depending on the selected input data). Select a range for the calculation from this list. Only ranges with at least three values are shown, because the minimum number of values for the curve analysis is three. To view, create or change a range, press the [Ranges] button to open the range window. You can also define an individual range, where the start and/or stop value is not fixed. Select the last entry (Individual Range) in the drop down list to use and define individual range. Read more about individual ranges in the chapter 4.1: Ranges.

**Smooth method:** Select the smooth method you want to perform:

**Available methods:**

- **Moving average:** Calculates the smoothed curve using a window of a defined width that slides over the curve and calculates the average of the values inside the windows.

- **Number of moving Intervals:** Enter the number of intervals used for the moving window over the curve (box car width). The number must be odd and minimum three. The maximum number is defined by the number of values in the selected range minus one.

- **Exponential smoothing:** Calculates the smoothed curve using an adapted form of the double exponential smoothing method.

- **Smooth intensity:** Enter a number between 1 for weak smoothing and 99 for extreme smoothing. A good smooth intensity is between 60 and 80.

You can open a preview window to see how entered smoothing parameters affect the curve. Press the [Preview] button to open the preview window.

### 4.7.1 Preview of the smoothed curve

After pressing the preview button you see a window containing a graph with the smoothed curve:

The preview shows the curve and the smoothed curve of the first used well. The thin curve is the original curve, the thicker curve is the smoothed curve.

Move the slider on the left to change the width of the moving window (box car) - if the selected method is moving average - and see how this affects the smoothing of the curve(s). If you’ve found the best width, press OK to take this value as parameter on the calculation window.

You can change the displayed well if you change the selected entry of the drop down list Select Well.

**Note:** Pressing OK on the preview window will not perform the smoothing calculation. You have to press the Apply button on the calculation dialog in addition.

### 4.8 Kinetic Calculations

The kinetic calculations page is only enabled if the test run contains kinetic data.

**Input data:** Select the input data for the kinetic calculation. This can be the raw data or the result of any calculation that obtains kinetic data.

- **Kinetic range:** The input data for a kinetic calculation are always defined by the first cycle/interval and the last cycle/interval of a range. It is possible to have one or more ranges defined over your kinetic. The full range is always available and covers the total measurement. See in the chapter 4.1: Ranges, how to use and define a range. All defined ranges are listed in the drop down list with their start and stop cycle/interval. Select a range for the calculation from this list. To view, create or change a range, press the [Ranges] button to open the range window. You can also define an individual range, where the start and/or stop cycle/interval is not fixed. Select the last entry (Individual Range) in the drop down list to use and define individual range. Read more about individual ranges in the chapter 4.1: Ranges.

- **Calculation method:** Select the calculation method for your kinetic calculation.

  **Available methods:**

  - **Slope:** Calculates the linear regression curve for the kinetic points in the selected range and gives the corresponding slope value for each well. If slope is selected in the method list, a further drop down list appears beside the list to select the units for the result: The list contains five entries: **slope/hour, slope/min, slope/sec, slope/ms, slope/μs**.

  - **Time to threshold:** Calculates the time taken from the first cycle/interval in the selected range for the curve to reach a given threshold for each well. Enter the threshold value in the entry field **Threshold**, this option appears beside the method drop down list when this method is selected. If a kinetic curve does not reach the entered threshold, n.a. will be printed as result. You can define, what you want to see instead of n.a. in the result table with the **Result, if threshold is not reached** drop down menu.

  - **Time to max:** Calculates the time taken for the maximum value to be reached in the selected range for each well.

  - **Sum:** Calculates the sum of all kinetic points within the selected range for each well.

  - **Average:** Calculates the average of all kinetic points within the selected range for each well.

  - **Maximum:** Finds the maximum value of all kinetic points within the selected range for each well.
Minimum: Finds the minimum value of all kinetic points within the selected range for each well.

Standard deviation n: Calculates the standard deviation based on an entire population (in this case all kinetic points in the selected range for each well). The standard deviation is a measure of how widely values are dispersed from the average value. The SD n value is calculated by the following formula:

\[ \text{SD n} = \sqrt{\frac{\sum (x - \bar{x})^2}{n}} \]

Standard deviation: Calculates the standard deviation based on samples (in this case all kinetic points in the selected range for each well). The SD value is calculated by the following formula:

\[ \text{SD} = \sqrt{\frac{\sum (x - \bar{x})^2}{n-1}} \]

Note: The standard deviation n is the recommended standard deviation method, because the measured data applies to an entire population and not just samples.

%CV n: Calculates the standard deviation n of all kinetic points in the selected range for each well divided by the average of all kinetic points in the selected range for each well, and multiplies this number by 100 to express the result as a percentage.

%CV: Calculates the standard deviation of all kinetic points in the selected range for each well divided by the average of all kinetic points in the selected range for each well, and multiplies this number by 100 to express the result as a percentage.

Maximum of slope: Finds the maximum slope value of all kinetic points within the selected range for each well. The slope is calculated using the entered width: A linear regression fit with the number of cycles/intervals entered in the width entry is performed starting with the first cycle/interval of the range up to the last. The maximum value of all calculated slopes is the result. You can decide with the Slope Direction control whether the rising or the falling maximum value should be calculated.

Time to max slope: Calculates the time taken for the maximum slope value to be reached in the selected range for each well. Use the same controls as for Maximum of slope to define the calculation width and the slope direction.

Median: Finds the median value of all kinetic points in the selected range for each well. The median is described as the number separating the higher half of the values from the lower half. The median is found by arranging all kinetic values in the defined range of one well from lowest value to highest value and picking the middle one. If there is an even number of values, the median is not unique, so the mean of the two middle values is taken.

Cycle/Interval index at...: Like the time to max, time to threshold or time to max slope method, you can have the same calculations with the cycle/interval index instead of the time value as result. This can be useful in combination with individual ranges, if you want to use this index as a start or stop value for a range for further calculations. If a kinetic curve does not reach the entered threshold, n.a. will be used as result. You can define, what you want to use instead of n.a. in the result table with the Result, if threshold is not reached

If one of the methods Time to... was selected, you can define whether the start time for the time to calculation should be from begin of the measurement or the start time of the range for this calculation.

4.9 Kinetic Fit Calculations

The kinetic fit calculation page allows you to perform a formula fit based on a range of a signal curve. The fit will be calculated for each measured well in the plate. Each well has its own result fit curve and (optional) result fit parameter(s).

The result of each calculation is a fitted curve in the defined range which can be used like any other signal curve for further calculations. Outside the defined range, the original signal curve remains.

Note: You can combine different fit methods in one signal curve if you define different non overlapping ranges and calculate the different fit methods in the different ranges, using one fit calculation result as input data for the next one.

Input data: Select the input data for the calculation. This can be the raw data or the result of any calculation that obtains kinetic data.

Kinetic range: The input data for a kinetic fit calculation are always defined by the first cycle/interval and the last cycle/interval of a range. It is possible to have one or more ranges defined over your kinetic. The full range is always available and covers the entire measurement. See in the chapter 4.1: Ranges, how to use and define a range. All defined ranges are listed in the drop down list with their start and stop cycle/interval. Select a range for the calculation from this list. To view, create or change a range, press the button to open the range window. You can also define an individual range, where the start and/or stop cycle/interval is not fixed. Select the last entry (Individual Range) in the drop down list to use and define individual range. Read more about individual ranges in the chapter 4.1: Ranges.

Fit method: Select the curve fitting method for the calculation. Each curve fitting calculation has a set of parameters that describes the fit result. You can define which parameter should be used as result. See Select fit parameters / enter aliases below. Some of the fit methods have different fit formulas, if the x or y values should be logarithmic. For these fit methods you will find an entry in the drop down list for each combination of logarithmic and non-logarithmic x or y values, where a different fit formula is used. Below the drop down list you see the selected fit formula.
Available methods:

**Linear regression fit**: Calculates a straight line through the kinetic range with minimum \( r^2 \) value. The result describes the line with the parameters \( m \) (slope) and \( b \) (offset):

\[
y = mx + b
\]

**Logarithmic fit**: Calculates a logarithmic curve through the kinetic range with minimum \( r^2 \) value. The result describes the curve with the parameters \( m \) (scale) and \( b \) (offset):

\[
y = m \log(x) + b
\]

**Exponential fit**: Calculates an exponential curve through the kinetic range with minimum \( r^2 \) value. The result describes the curve with the parameters \( k \) and \( b \):

\[
y = e^{kx} + b
\]

**Double logarithmic fit**: Calculates a logarithmic curve through the kinetic range with minimum \( r^2 \) value, where the \( y \) values are also logarithmic. The result describes the curve with the parameters \( m \) and \( b \):

\[
\log y = m \log x + b
\]

\[
y = e^{m \log x + b} = 10^b
\]

**4-Parameter fit**: Calculates the dose response curve in the kinetic range with minimum \( r^2 \) value. Result parameters are **Bottom**, **Top**, **Slope**, **IP** (point of inflection) for the formulas (the first one for logarithmic \( y \) values, the second one for linear \( y \) values):

\[
y = \text{Top} \times \left( \frac{\text{IP}}{\text{Bottom}} \right)^{\frac{x}{\text{Slope}}}
\]

\[
y = \text{Top} \times \frac{\text{IP} - \text{Bottom}}{1 + \left( \frac{x}{\text{Slope}} \right)}
\]

**5-Parameter fit**: Calculates the dose response curve with a symmetry factor in the kinetic range with minimum \( r^2 \) value. Result parameters are **Bottom**, **Top**, **Slope**, **IP** (point of inflection), **Symmetry** for the formulas (the first one for logarithmic \( y \) values, the second one for linear \( y \) values):

\[
y = \text{Bottom} \times \left( \frac{\text{IP}}{\text{Bottom}} \right)^{\frac{x}{\text{Slope}}}
\]

\[
y = \text{Bottom} \times \frac{\text{IP} - \text{Bottom}}{1 + \left( \frac{x}{\text{Slope}} \right)^{\text{Symmetry}}}
\]

If the 4-Parameter fit or the 5-Parameter fit is selected, additional controls appear on the window:

- **Predefine Fit Parameter**: Check this control to predefine the **Top** and **Bottom** value of the fit. Enter a value for **Top** and **Bottom**.

**Segmental regression fit**: The segmental regression divides the kinetic range into two segments and calculates a linear regression for each segment. The result of the fit is the result of each linear regression and the intersection point of the two lines. Each combination of logarithmic and linear \( x \) and \( y \) values has its own fit formula:

- \( y = mx + b \)
- \( y = m \log x + b \)
- \( \log y = mx + b \)
- \( \log y = m \log x + b \)

**2nd polynomial fit**: Calculates a quadratic polynomial curve according to the kinetic range. The result parameters are \( b \) (offset), \( c_1 \) (multiplier 1) and \( c_2 \) (multiplier 2) for the fit formulas:

\[
y = b + c_1 \log x + c_2 (\log x)^2
\]

**3rd polynomial fit**: Calculates a third order polynomial curve according to the kinetic range. The result parameters are \( b \) (offset), \( c_1 \) (multiplier 1), \( c_2 \) (multiplier 2) and \( c_3 \) (multiplier 3) for the fit formulas:

\[
y = b + c_1 \log x + c_2 (\log x)^2 + c_3(\log x)^3
\]

**Hyperbola fit**: Calculates a hyperbola in the kinetic range with minimum \( r^2 \) value. Each combination of logarithmic and linear \( x \) and \( y \) values has its own fit formula:

\[
y = \frac{mx}{b + x}
\]

**User defined fit**: Define your own fit formula, if none of the predefined formulas fulfill your requirement. If this entry is selected, a button **Edit Formula**... appears. Click on this button to define the formula and the fit parameters. Details are explained in the chapter 4.26 **User defined fit formulas**.

**Select fit parameters / enter aliases**: In addition to the fit result curve you can create a result node for each available fit parameter. Check the check box control for the parameters you want to use as result. If you want to use a different name for the result parameter, enter the alias name in the entry field beside the parameter.

After performing the calculation new nodes appear in the navigation tree. One for the fitted curve and one for each result parameter you have selected:

### 4.10 Standard Calculations

The standard calculation page is only enabled if the layout of the test run contains standards. If the test run is a kinetic measurement, a kinetic calculation must be performed first to enable the standard calculation page. If the test run is a measured spectrum, at least one discrete wavelength must be added to the test run, to enable the standard calculation page.
Input data: Select the input data for the standard calculation. This can be the result of any calculation generating end point data. If the selected input data has kinetic data, you need to select the cycle/interval to define the data base for the fit. If the layout contains replicates of the standards and the selected is not based on a replicate calculation, you can define that the calculation is based on the average of the replicates if you check the control use average of replicates to calculate the standard curve.

Calculation method: Select the curve fitting method for the standard calculation. Each curve fitting calculation has a set of parameters that describes the fit result and is used for the concentration recalculation of the samples. See the section Fit Results below for more information.

Available methods:

**Linear regression fit**: Calculates a straight line through the standards with minimum $r^2$ value. The result describes the line with the parameters $m$ (slope) and $b$ (offset):

$$y = mx + b$$

If **force line through zero** is selected the linear regression fit calculates a straight line with $Y=0$ for $X=0$:

$$y = mx$$

**4-Parameter fit**: Calculates the dose response curve for the standards. Result parameters are Bottom, Top, Slope, EC50/IC50 and $\log(EC50)/\log(IC50)$ for the formula:

$$y = Bottom + \frac{Top - Bottom}{1 + \left(\frac{X}{Slope}\right)^n}$$

The variable IP (point of inflection) in the Formula is the Inflection point value. The EC50/IC50 is the concentration value where the signal is in the middle between Top and Bottom. The first formula is used if logarithmic Y values are used, the second is for linear Y values (see **Linear or logarithmic X / Y Values below**)

**advanced 5-Parameter fit**: Select the 5-Parameter fit method and click the **Use advanced 5 parameter fit** to get this calculation method. It calculates the dose response curve with a symmetry parameter for the standards, but without moving the point of inflection. Result parameters are Bottom, Top, Slope, EC50/IC50, $\log(EC50)/\log(IC50)$ and Symmetry for the formula:

$$y = Bottom + \frac{Top - Bottom}{1 + \left(\frac{X}{Slope}\right)^n}$$

The variable IP (point of inflection) in the Formula is the EC50/IC50 value. The first formula is used if logarithmic Y values are used, the second is for linear Y values (see **Linear or logarithmic X / Y Values below**)

If the 4-Parameter fit or the 5-Parameter fit is selected, additional controls appears on the window:

**Use EC/IC**: Defines if EC or IC value should be calculated.

**Predefine Fit Parameter**: Check this control to predefine the Top and Bottom value of the fit. Enter a value for Top and Bottom.

**Cubic spline fit**: A spline is a special function defined piecewise by polynomials. The cubic spline calculates polynomial fit curves between two adjacent standards. The result is a continuous and differentiable curve with each standard lying on the curve. Therefore the result is not just one formula but a set of polynomial formulas and $r^2$ is always 1.

**Point to point**: The point to point fit calculates linear regression fits between two adjacent standards. The result is in fact a continuous but not a differentiable curve. Each standard is lying on the curve therefore the result $r^2$ is 1.

**Segmental regression fit**: The segmental regression divides the standards into two segments and calculates a linear regression for each segment. The result of the fit is the result of each linear regression and the intersection point of the two lines.

**2nd polynomial fit**: Calculates a quadratic polynomial curve according to the standards. The result parameters are $b$ (offset), $c1$ (multiplier 1) and $c2$ (multiplier 2) for these fit formulas (one formula for each combination of linear and logarithmic X and Y values. See **Linear or logarithmic X / Y Values below**):

$$y = b + c1x + c2x^2$$

$$\log(y) = b + c1 \log(x) + c2(\log(x))^2$$

$$\log(y) - b + c1x + c2x^2$$
3rd polynomial fit: Calculates a third order polynomial curve according to the standards. The result parameters are \( b \) (offset), \( c1 \) (multiplier 1), \( c2 \) (multiplier 2) and \( c3 \) (multiplier 3) for these fit formulas (one formula for each combination of linear and logarithmic X and Y values. See Linear or logarithmic X / Y Values below):

\[
\begin{align*}
    y & = b + c1x + c2x^2 + c3x^3 \\
    y & = b + c1 \log x + c2(\log x)^2 + c3(\log x)^3 \\
    \log y & = b + c1 \log x + c2(\log x)^2 + c3(\log x)^3 \\
    \log y & = b + c1x + c2x^2 + c3x^3
\end{align*}
\]

Hyperbola fit: Calculates a hyperbola for the standards with minimum \( r^2 \) value. The result parameters are \( m \) and \( b \) for these fit formulas (one formula for each combination of linear and logarithmic X and Y values. See Linear or logarithmic X / Y Values below):

\[
\begin{align*}
    y & = \frac{mx}{b+x} \\
    y & = \frac{m \log x}{b+\log x} \\
    \log y & = \frac{m \log x}{b+\log x} \\
    \log y & = \frac{mx}{b+x}
\end{align*}
\]

User defined fit: Define you own fit formula, if none of the predefined formulas fulfill your requirement. If this entry is selected, a button Edit Formula... appears. Click on this button to define the formula and the fit parameters. Details are explained in the chapter 4.26: User defined fit formulas.

Linear or logarithmic X / Y Values: Use the check boxes available to define whether the fit result is shown using either linear or a logarithmic scaling for the adjusting axes.

Depending on the X and Y Values, a logarithmic calculation may not be possible (i.e. for values \( x \leq 0 \)). In this case the hint Calculation of fit parameters not possible appears where the fit result parameters are normally shown.

Note: Using logarithmic X values will influence the fit result of a point to point fit, a linear regression fit and a segmental regression fit. Using logarithmic Y values will influence the fit result of all fit methods.

Use dilution factor for standards calculation: This option appears if there is at least one dilution factor \( > 1 \) defined in the layout. If this checkbox is checked, the dilution factor is used for the recalculation of the concentration values meaning that the result will be multiplied by the dilution factor defined

Use result of group ... for calculation: This option appears if you have more than one group with standards. It is possible to select that the standard fit result of one group be used for the recalculation for all other groups. If the ‘-’ entry is selected then every group will use its own fit result for the recalculation of the concentration values.

Don't use wells exceeding limitations for recalculated concentrations (toggle out): If this option is set, a well will be automatically toggled out, if a concentration value cannot be calculated with the resulting fit formula and the value of the well or if the recalculated concentrations exceed the limitations (see Limitations for Recalculated Concentrations). Standards used to calculate the fit will not be toggled out, because this would change the fit.

Weighted fit

Check this control if the weight of each standard should not be the same. You can give less weight to less precise standards and more weight to more precise standard. Select one of the offered weighting methods to define, how the weighting for each standard should be calculated.

Confidence Interval Settings

For all fit methods except the point to point and the cubic spline fits, confidence intervals and confidence band are calculated automatically. Confidence intervals are calculated for each standard and for each fit result parameter. The confidence band can be displayed in the standard curve chart together with the error bars. The confidence values for the fit result parameters are displayed as two additional columns in the fit result table.

CI percentage: Define the percentage value for the confidence interval calculation. A lower value results in a wider interval band.

Prediction Bounds Settings: Select between the different settings:

Observation or Function Bounds: Provides a confidence interval for a new observation or for a new function (curve). In general, observation intervals are wider than function intervals, because of the additional uncertainty of predicting a new response value (the function plus random errors).

Non-simultaneous or Simultaneous Bounds: Provides a confidence interval using a single predictor value (non-simultaneous) or all predictor values (simultaneous). In general, simultaneous intervals are wider than non-simultaneous intervals, because of the additional uncertainty of bounding values for all predictors.

4.10.1 Fit Result

After performing a standard curve fit, the fit result can then be inspected on the standard curve chart. If this is the first standard calculation of the test run, the tab for the standard curve page will appear following a successful fit.

If a fit fails for a group of standards of the test run, the hint Calculation of fit parameters not possible appears on the detailed window for the fit result and on the fit result window. The reason for a failed fit could either be a wrong axis scaling (logarithmic instead of linear), or a less number of standards to calculate the fit (see Limitations for Recalculated Concentrations).

If the calculation of a concentration value fails for a well, you will see in the microplate or table view a text message that indicates the reason for the failure:

In the microplate and the table view, the result of the concentration calculation for the contents, based on the fit result will be displayed.

<table>
<thead>
<tr>
<th>Text</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>n.a.</td>
<td>Not available - recalculation not possible (normally the fit itself was not possible)</td>
</tr>
<tr>
<td>&lt;&lt; std range</td>
<td>The calculated concentration value is under the defined limit for this calculation method. (see Limitations for Recalculated Concentrations table below)</td>
</tr>
<tr>
<td>&gt;&gt; std range</td>
<td>The calculated concentration value is above the defined limit for this calculation method. (see Limitations for Recalculated Concentrations table below)</td>
</tr>
<tr>
<td>&lt;&lt; Y range</td>
<td>The input value is either under the domain of the fit or under the defined limit for this calculation method. (see Limitations for Recalculated Concentrations table below)</td>
</tr>
<tr>
<td>&gt;&gt; Y range</td>
<td>The input value is either above the domain of the fit or above the defined limit for this calculation method. (see Limitations for Recalculated Concentrations table below)</td>
</tr>
<tr>
<td>ambiguous</td>
<td>The input value is ambiguous, that means that it fits to more than one concentration value.</td>
</tr>
</tbody>
</table>

Limitations for Recalculated Concentrations:

<table>
<thead>
<tr>
<th>Fit method</th>
<th>min. no. of standards</th>
<th>concentration minimum</th>
<th>concentration maximum</th>
<th>input (y) minimum</th>
<th>input (y) maximum</th>
</tr>
</thead>
</table>
### 4.12 Data Calculations

The data calculation page \( \frac{1}{2} \) allows you to perform arithmetic operations between either two different data inputs or between two sets of wavelength data for the same data input.

First input data: Select the first input data for the data calculation. This can be the result of any calculation which outputs the data as numbers.

Second input data: Select the second input data for the data calculation. This can be the result of any calculation which outputs the data as numbers.

Wavelength: If the selected input data has more than one measured wavelength, it is possible to select the wavelength on which the calculation should be performed. If you select the entry All in the list, the calculation will be performed for each wavelength (wavelength 1 of the first input data with wavelength 1 of the second input data, wavelength 2 of the first input data with wavelength 2 of the second input data and so on). If the selected input data contains spectra data and you select spectrum, the calculation will be done based on the spectrum curve and the result is again a spectrum curve.

Kinetic Parameters: If the selected input data contains kinetic data, the Kinetic Parameters controls are visible and can be used to define how to handle the kinetic data:

- **Cycle/Interval**: select a certain cycle to use only this value for the calculation. Select all, to do the calculation for all cycles (the result is then a kinetic curve).
- **Range**: Select a range and a calculation to calculate a certain value for the cycles/intervals in the range and use this value for the data calculation.
- **Multiplier**: Enter a multiplier for the calculation.

Calculation: Select the calculation method for your data calculation.

Available methods: \( \textit{minus}, \textit{divided by}, \textit{plus}, \textit{multiplied by} \).

**values as percentage**: This control appears, if the selected calculation method is ‘\textit{divided by}’. Select it to calculate the ratio as a percentage value. The **Multiplier** will then be set to 100 and the resulting unit is %.

**Resulting unit**: Select the unit type of the calculation result.

### 4.13 Validations

The validations page \( \text{\textit{\&}} \) lets you classify your data. Similar to the color modes for the \textit{Microplate View}, the data can be grouped into good or bad (pass or fail) categories:
Input data: Select the input data for the validation. This can be the result of any calculation which outputs the data as numbers.

**Mode**: select the kind of validation: good / bad, good / bad / unknown, gradient or delta band.

For each measured wavelength you can enter a threshold (for the good / bad mode) or a lower and an upper threshold (for the good / bad / unknown mode) or a start and a stop value (for the gradient mode) or threshold and a delta band value (for the delta band mode). Enter a threshold value that divides the good from the bad data or defines the lower and upper boundary of your classification. You can also select contents out of the pull down list that defines the threshold value. Use the %off entry field to define a percentage of a content value (e.g. 20 % of the blank value). In the delta band mode, you define a threshold and a delta value which defines a range around the threshold. You can also define if the delta range is an absolute value or a percentage of the threshold value.

**Display**: Text and background color is defined here that will be shown with the result of the classification. For the good / bad and the good / bad / unknown modes, you can define if wells, exceeding the defined thresholds should not be used further on. Therefore the drop down list for the displayed text has the entry *Don't Use Well*.

If *Don't Use Well* is selected, the subjacent color control changes to a list control that allows you to define if only wells with special contents should be set to unused.

Another special meaning has the entry *Value*. If this item is selected, the value of the well for the selected input data is displayed together with the selected color as background.

If **gradient** mode is selected, the drop down list contains the additional entry **Percentage**. If you select this entry, not the value but a percentage representation of the value based on the entered start and stop values will be displayed.

≤ or < (Lower) **Threshold** (not for the gradient mode or delta band mode): Select the text displayed for the values under/equal to the (lower) threshold out of the drop down list, or enter any text into the entry field and select an according background color.

≥ or > (Upper) **Threshold** (only for the good / bad / unknown mode): Select the displayed text for the values above the (upper) threshold out of the drop down list, or enter any text into the entry field and select an according background color.

between **Lower Threshold** and **Upper Threshold** (only for the good / bad / unknown mode): Select the displayed text for the values between the lower and the upper threshold out of the drop down list, or enter any text into the entry field and select an according background color.

**Start Color / End Color** (only for the gradient mode): Select the background color for the start and for the stop value. All values between these two values will be displayed with a background color between the two selected colors according to the percentage of the position of the value between the start and the stop value. Select Rainbow colors if the background color should follow the color of the rainbow spectrum.

**Outside Band / Inside Band** (only for the delta band mode): Select the displayed text and background color for values outside the defined delta value around the threshold and for values inside the defined band.

### 4.14 Assay Quality

The assay quality calculations page provides several methods to analyze your measurement.

**Input data**: Select the input data for calculating the assay quality. This can be the raw data or the result of any calculation.

**Calculation method**: Select the calculation method for your assay quality.

**Available methods**:

**Z' (Z Prime)**: Calculates the Z prime value based on the reference contents you define. Select a content out of each drop down list for each of the data on which the Z prime calculation is based on. The formula for the calculation is:

\[ Z' = 1 - \frac{3 \cdot \sigma_1 + 3 \cdot \sigma_2}{|\mu_1 - \mu_2|} \]

- \( \mu_1 \) is the average of the values over the replicates of the first reference content
- \( \sigma_1 \) is the standard deviation over the replicates of the first reference content
- \( \mu_2 \) is the average of the values over the replicates of the second reference content
- \( \sigma_2 \) is the standard deviation over the replicates of the second reference content.

**Signal to blank**: Calculates the Signal to blank ratio for each well. You can select the content which represents the blank value with the **select blank** drop down list. If the layout contains blanks, it will be preselected. The formula for the calculation is:

\[ S / B = \frac{\mu_{signal}}{\mu_{background}} \]

- \( \mu_{signal} \) is the average of the values over the replicates of the content for which the S/B value is calculated.
- \( \mu_{background} \) is the average of the values over the replicates of the blank.
Signal to noise: Calculates the Signal to noise ratio for each well. You can select the content which represents the noise value with the select noise drop down list. If the layout contains blank, it will be pre-selected. The formula for the calculation is:

\[
S / N = \frac{\bar{x}_{\text{signal}} - \bar{x}_{\text{background}}}{\sqrt{\sigma_{\text{signal}}^2 + \sigma_{\text{background}}^2}}
\]

\(\bar{x}_{\text{signal}}\) is the average of the values over the replicates of the content for which the S/N value is calculated.

\(\sigma_{\text{signal}}\) is the standard deviation over the replicates of the content for which the S/N value is calculated.

\(\bar{x}_{\text{background}}\) is the average of the values over the replicates of the noise (blank).

\(\sigma_{\text{background}}\) is the standard deviation over the replicates of the noise (blank).

Note: It is important to have enough replicates for a reasonable Z', Signal To Blank or Signal To Noise calculation. Make sure that the input data for these calculation methods are NOT the result of a replicate statistic or based on a replicate statistic!

Percentage calculation: Set the value of each well in a percentage relation between a 0% and a 100% reference. You can select the content which represents the 0% reference value and the content which represents the 100% value. If the 0% value or the 100% value should be a fixed number (like 0% = 0), you can enter the value in the related entry field.

In addition, you can enter a percentage value to use e.g. 90% of the 100% reference or 110% of the 0% reference. The formula for the calculation is:

\[
V_{\%} = \frac{\bar{x}_{\text{Signal}} - \bar{x}_{\text{Blank}}}{\bar{x}_{\text{100\%}} - \bar{x}_{\text{0\%}}} \times 100
\]

\(\bar{x}_{\text{Signal}}\) is the average of the values over the replicates of the 0% reference.

\(\bar{x}_{\text{Blank}}\) is the average of the values over the replicates of the 100% reference.

Group Handling: If the layout of the test run contains groups, you have to decide how groups are handled:

<table>
<thead>
<tr>
<th>Use selected content for all groups</th>
<th>Use the selected content of a group for the calculation even if the calculated well is in a different group.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Calculate for each group</td>
<td>Use the selected content of the group of the calculated well. If the group of the well does not have the selected content, no calculation is done for that well.</td>
</tr>
<tr>
<td>Ignore groups</td>
<td>Ignore the groups and calculate the result as if no groups where defined.</td>
</tr>
</tbody>
</table>

4.15 User Defined Formula

The user defined formula calculation page allows you to define and perform arithmetic operations based on an entered equation. The result of the equation for each well defines the result data of the created process.

Input data: Select the input data for the data calculation. This can be the result of any calculation which outputs the data as numbers. The input data defines the used X value in the formula for each well and each wavelength (if the input data comes with more than one wavelength).

Calculate for contents: Select the contents for which the formula is valid. The formula is applied and calculated for all wells containing the selected contents. You can select one or more contents in the drop down menu.

Result name: Enter a name that identifies the formula process. The name defines the name of the process and node name of that process in the navigation tree.

4.15.1 Enter a formula

Formula: The field formula shows the entered formula. The color frame and the text below the field show if the formula is valid. A syntax check is performed after each entry made into the formula.

<table>
<thead>
<tr>
<th>Color</th>
<th>Text</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>green</td>
<td>Formula valid</td>
<td>The formula is valid. The apply button is enabled and can be pressed if the formula is completely entered.</td>
</tr>
<tr>
<td>orange</td>
<td>Formula incomplete / Open bracket</td>
<td>The formula is incomplete. An operator or a parameter for an operator is missing or a bracket is not closed. Please complete the formula.</td>
</tr>
<tr>
<td>red</td>
<td>Syntax error</td>
<td>The combination of the entered operators, variables and constants is not valid. Please correct the entry to make the formula valid.</td>
</tr>
</tbody>
</table>

Use the operator buttons, the entry fields and the drop down menus (see description below) to enter the formula. Numbers and simple operators can also be typed in directly in the formula field. You can set the cursor in the field with the mouse and you can delete entries with the backspace and the DEL key on the keyboard.

Description of the buttons above the formula entry field:

<table>
<thead>
<tr>
<th>Button</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ü</td>
<td>Undo the last step(s).</td>
</tr>
<tr>
<td>←</td>
<td>Sets the cursor one position to the left.</td>
</tr>
<tr>
<td>→</td>
<td>Sets the cursor one position to the right.</td>
</tr>
<tr>
<td>DEL</td>
<td>Deletes the content (an operator, bracket, variable or constant value) on the left side of the cursor (if you move the mouse over the button, the content that will be deleted is marked with a blue background).</td>
</tr>
<tr>
<td>Reset Formula</td>
<td>Clears the formula entry field.</td>
</tr>
</tbody>
</table>
Adding operators and brackets to the formula (operator buttons):

To add operators to the formula press the according operator button. The operator will be inserted at the current cursor position. If an operator has two parameters (like division) the operator must be between these two operators, e.g. x / S1 (first enter the x, using the x (well value) button, then press the division operator button, and then enter the S1, using the content drop down menu (how to enter variables and constant values see below). If the operator has one parameter, the parameter for most of these operators is behind the operator only for the x² operator, the parameter comes before the operator and for brackets the parameter is enclosed between the brackets. A parameter can be a variable, a constant value or a formula on its own (enclosed in brackets if needed).

<table>
<thead>
<tr>
<th>Operator Button</th>
<th>No. Parameters</th>
<th>Operator description</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>2</td>
<td>Multiplication between the two parameters</td>
</tr>
<tr>
<td>/</td>
<td>2</td>
<td>Division: First parameter is the numerator; second parameter is the denominator.</td>
</tr>
<tr>
<td>+</td>
<td>2</td>
<td>Addition between the two parameters</td>
</tr>
<tr>
<td>-</td>
<td>2</td>
<td>Subtraction between the two parameters</td>
</tr>
<tr>
<td>^</td>

<td>Calculates the logarithm based on 10 ( ( \log_{10}(x) )) of the parameter</td>
</tr>
<tr>
<td>abs</td>
<td>1</td>
<td>Calculates the absolute value of the parameter (e.g. -5 remains 5, but 5 becomes 5)</td>
</tr>
<tr>
<td>sqrt</td>
<td>1</td>
<td>Calculates the square of the parameter.</td>
</tr>
<tr>
<td>2sqrt</td>
<td>1</td>
<td>Calculates the square root of the parameter.</td>
</tr>
<tr>
<td>1/x</td>
<td>2</td>
<td>Calculates the power of the two parameters. The first parameters is the mantissa, the second is the exponent of the power calculation.</td>
</tr>
<tr>
<td>-1</td>
<td>1</td>
<td>Negates the parameter: -5 becomes 5 but 5 becomes -5</td>
</tr>
<tr>
<td>(</td>
<td>1</td>
<td>Encloses the parameter in brackets.</td>
</tr>
</tbody>
</table>

Adding variables and constant values to the formula:

You cannot add constant values or variable names directly into the formula field with the keyboard. Use the controls described in this section instead to enter your formula. The value or variable will be inserted at the current cursor position in the formula entry field.

Fix value

Use the entry field to enter fix number values. Press the OK button beside the field to add the value to the formula.

Content

Open the drop down menu and select a content. Press the OK button to add the content as a variable to the formula. The value of the content, valid for the selected input data will be used in the formula. If replicates are available, the average value over the replicates is used. For each group of contents (Standards, Samples...), there is a separate entry with the extension _iterate over, indicated with a # after the content type letter (S#, X#, ...) in the formula. Select this content, if the index of the content should follow the index of the content of the well, for that the value is calculated. Example: If the formula is x-S# and the wells content is X2, the value of S2 will be used at the position of S8 in the formula (X2-S2 will be calculated for that well).

If the layout contains groups, a further drop down menu appears on the right side of the content drop down menu. You can select between certain group, <ignore group> or <calculate for each>:<ignore group>: The average of all the wells with the selected content over all groups will be calculated and used in the formula. The variable in the formula is marked with an i: S1i, or X2i...<calculate for each>: The average of the wells with the selected content of the group for the current well will be calculated and used in the formula (if the result for a well of group A is calculate, the average of the content for group A is used, if the result for a well of group B is calculated, the average of the content for group B is used, and so on). The variable in the formula has no further mark: S1, X2...

GROUPNAME: The average of the wells with the selected content of the group GROUPNAME will be used in the formula, regardless of the group of the currently calculated well. The variable in the formula is marked with the name of the group: S1A, X2B...

Well

Open the drop down menu and select a well. Press the OK button to add the well as a variable to the formula. The value of the well, valid for the selected input data will be used in the formula.

Add x = input data

The variable x will be added to the formula, when you press this button. X is replaced with the value, valid for the selected input data of the currently calculated well, when the formula is applied.

dilution of x

The term dil(x) will be added to the formula, when you press this button. Dil(x) is replaced with the dilution value of the currently calculated well. If no dilution values were defined, a dilution of 1 is used.

concentrati on of x

The term conc(x) will be added to the formula, when you press this button. Conc(x) is replaced with the concentration value of the currently calculated well, if available/defined. If the well is not a standard with concentration value, no calculation for this well is done.

value... or variable or value...

Press this button to add a value that comes from any other calculation in this test run or a variable to the formula. Read the chapter 4.2.1: Define and Use Variables to see, what variables and values are and how to use them. In the formula, variables are displayed as V1, V2, V3,..., values are displayed as C1, C2..., W1, W2,... if they represent content or well values. If the value represents a fit result parameter, the name of the parameter is displayed in the formula. If you move the mouse over a variable or a value in the formula, you get a detailed hint with information about the variable or value.

OD(nm)

Returns the OD value for a given Lambda value in nm if the value is in the valid range of the measured spectrum (only for Spectrum measurements).

nm(Y)

Returns the nm value of the given Y value of the spectrum curve. The nm value is the value of the index which is the nearest to the given Y value (only for Spectrum measurements).

A in nm

If the selected input data is a spectral scan, the current wavelength value of the iteration over the wavelength will be used in the formula.

Y(time)

Returns the signal value of a given time value if the time value is in the valid range of the measured kinetic (only for kinetic measurements).

time(Y)

Returns the time value of the given Y value of the signal curve. The time value is the value of the index which is the nearest to the given Y value (only for kinetic measurements).

In s

If the selected input data has kinetic data, the current time value of the iteration over the time will be used in the formula.

Resulting unit: Enter the resulting unit of the entered formula. This can be any entered text or you can select one of the entries of the drop down menu: Use the entry Same as input data, if the unit of the formula result is the same as the unit of the input data. Select none if the formula has no unit or you don’t know the unit.

Note: The selected unit affects the used format to display the numbers. See chapter 3.24.5: Number Format Settings.

4.15.2 Export and Import a Formula

If a formula is valid it can be exported to a file to save it and use it for further test runs. To use a previously saved formula you can import the formula:
4.16 Enzyme Kinetic Calculations

The enzyme kinetic calculation page is only enabled if it is a kinetic measurement and the layout of the test run contains standards. Read more about enzyme kinetic and how to set an experiment and use MARS to evaluate the measurement in Chapter 4.16.4: How to Perform an Enzyme Kinetic Experiment.

The enzyme kinetic calculation algorithm calculates the reaction velocity over the concentration first. Based on this it performs a hyperbola or a linear fit - depending on the selected calculation method - to evaluate Vmax and Km.

**Input data:** Select the input data for the enzyme kinetic calculation. This can be the result of any calculation that keeps the kinetic data.

**Wavelength:** If the selected input data comes with more than one wavelength (multi chromatic, dual channel or spectrum), select the wavelength for the calculation.

**Calculation method:** Select the desired enzyme kinetic equation to perform the fit of the reaction rate over the concentration.

**Available methods:**

- **Michaelis-Menten fit:** The saturation process describes a hyperbola. The Michaelis-Menten fit calculates directly the desired variables Km and Vmax based on this hyperbola:
  \[ \frac{V_{\text{max}}}{K_m + X} = \frac{Y}{X} \]
  Where \( Y \) is the reaction velocity and \( X \) is the concentration.

- **Lineweaver-Burk:** Transforms the plot of the reaction velocity (V) over concentration ([S]) to 1/V (Y-Axis) over 1/[S] (X-Axis) and performs a linear regression fit:
  \[ y = \frac{m}{x} + b \]
  Where \( V_{\text{max}} = 1/b \) and \( Km = m/b \)

- **Eadie-Hofstee:** Transforms the plot of the reaction velocity (V) over concentration ([S]) to V (Y-Axis) over V/[S] (X-Axis) and performs a linear regression fit:
  \[ y = mx + b \]
  Where \( V_{\text{max}} = b \) and \( Km = -m \)

**Scatchard:** Transforms the plot of the reaction velocity (V) over concentration ([S]) to V/[S] (Y-Axis) over V (X-Axis) and performs a linear regression fit:

\[ y = mx + b \]

Where \( V_{\text{max}} = -b/m \) and \( Km = -1/m \)

**Hanes-Woolf:** Transforms the plot of the reaction velocity (V) over concentration ([S]) to [S]/V (Y-Axis) over [S] (X-Axis) and performs a linear regression fit:

\[ y = mx + b \]

Where \( V_{\text{max}} = 1/m \) and \( Km = b/m \)

**Concentration unit:** Enter the concentration unit. If the concentration unit is already defined, you can see and change it here.

**Kinetic range:** Select the range for the calculation of the reaction velocity (maximum slope in the range). The full range is always available and covers the total measurement. See in the chapter 4.1 Ranges, how to define a range. All defined ranges are listed in the drop down list with their start and stop cycle/interval. Select a range for the calculation from this list. To view, create or change a range, press the button to open the range window. You can also define an individual range, where the start and/or stop cycle/interval is not fix. Select the last entry (Individual Range) in the drop down list to use and define and individual range. Read more about individual ranges in the chapter 4.1 Ranges.

**Reaction velocity:** Define if the reaction velocity is volume per microsecond, millisecond, second, minute or hour.

4.16.1 Define Enzyme Dilution Factor(s) and Extinction Coefficient(s)

**Enzyme Dilution Factor:** If the enzyme was diluted, enter the dilution factor in this field.

**for Group:** (only visible if the layout contains more than one group) If groups are defined, a dilution factor for each group can be entered (the control **Different dilution factor for each group** must be checked) or the same dilution factor for all groups can be used. To enter the dilution factor for a certain group, select the group with the drop down control and enter the desired factor.

**Enter Extinction Coefficient(s):** If this control is selected, the extinction coefficient to transfer the OD values to concentration volumes must be entered below. Read more about how to find out the extinction coefficient with MARS in chapter 4.16.4: How to Perform an Enzyme Kinetic Experiment.

**Calculate Extinction Coefficient(s):** If this control is selected, the extinction coefficient to transfer the OD values to concentration volumes are calculated automatically. Therefore a linear regression fit is performed on the last cycle/interval of the selected range, where the slope of the fit defines the coefficient. This is only possible in long-time enzymatic reactions in which the substrate is completely converted into product indicated by no more change in signal. Read more about how to find out the extinction coefficient with MARS in chapter 4.16.4: How to Perform an Enzyme Kinetic Experiment.

**Extinction Coefficient:** If **Enter Extinction Coefficient(s)** is selected above, this field is enabled and the extinction coefficient can be entered in this field.

**for Group:** (only visible if the layout contains more than one group) If groups are defined, an extinction coefficient for each group can be entered (the control **Different extinction coefficient for each group** must be checked) or the same
extinction coefficient for all groups can be used. To enter the extinction coefficient for a certain group, select the group with the drop down control and enter the desired value.

4.16.2 Consider zero concentration reaction
Subtract reaction of content with zero concentration: If you have a background reaction at concentration zero, that needs to be subtracted from the reaction with concentration, check this control and select the content which contains the substance with concentration zero with the next control.

Select the content with concentration zero: Select the content from the drop down list that contains the substance that shows the reaction with no concentration.

Group Handling: If the layout of the test run contains groups, you have to decide how groups are handled:

| Use selected content for all groups | Use the selected content of a group for the calculation even if the calculated well is in a different group. |
| Calculate for each group | Use the selected content of the group of the calculated well. If the group of the well does not have the selected content, no calculation is done for that well. |
| Ignore groups | Ignore the groups and calculate the result as if no groups were defined. |

4.16.3 Calculation Result
After performing an enzyme kinetic calculation, the result can then be inspected on the enzyme kinetic fit chart. If this is the first enzyme kinetic calculation of the test run, the tab for the enzyme kinetic fit curve page will appear following a successful calculation.

The calculated Vmax and Km values are displayed in the detailed window and can be displayed and exported on the enzyme kinetic fit result window.

In the microplate and the table view, the calculated reaction velocity for each well is shown for that calculation node.

4.16.4 How to Perform an Enzyme Kinetic Experiment
This chapter describes how to set an experiment and how to use the MARS Data Analysis software for the determination of Km and Vmax.

Outline
1. Definition of Km and Vmax
2. Preparation of the standard curve
3. Enzymatic measurements using different substrate concentrations
4. Evaluation using the MARS Data Analysis software

Definition of Km and Vmax
Km (Michaelis-Menten constant) is equivalent to the substrate concentration at which the reaction velocity reaches half of the maximal velocity. Km describes the affinity of enzymes to a specific substrate.

Vmax stands for the maximal velocity of an enzymatic reaction.

Preparation of the standard curve
A usual enzymatic reaction contains a substrate that is converted into a product with the help of an enzyme. To determine the conversion from substrate to product it is necessary that the substrate changes its spectral properties during the reaction. Either the substrate absorbs at a special wavelength and does not give a signal when it is converted to the product or the substrate gives no signal but the product does. The following figure shows a reaction example in which the product gives a measurable absorbance signal:

![Reaction Example]

The product pNP (p-nitro phenol) is a yellow substance and shows an absorbance maximum at about 410 nm whereas the substrate pNPA (p-nitro phenyl acetate) does not show any absorbance at 410 nm.

Self-made standard curve
Before the enzymatic measurement will start a standard curve of the substrate/product should be taken. The slope of the standard curve will later be necessary for the enzymatic kinetic calculations. An example for the pNP standard curve is given here:

![Self-made Standard Curve]

Software made standard curve
In case that the enzymatic reaction is run until the substrate is completely converted into the product, it is possible that the software creates the standard curve using the endpoint values of the wells. Please note that this option is only useful when the substrate is completely converted into the product indicated measurement values that are no longer increasing or decreasing (plateau). This kind of kinetic measurements usually take several hours.

Enzymatic measurements using different substrate concentrations

Usually equal amounts of enzyme solution and buffer are transferred into the wells. Different concentrations of substrate are added using the onboard injectors. A possible layout is given here:

![Enzymatic Measurements Layout]

The blank should contain everything except the enzyme. The negative control should contain everything except the substrate.

Evaluation using the MARS Data Analysis software
After measurement the results can be found in the MARS Data Analysis software. First it is necessary to take a look at the signal curve. An example is given here:
Choose a range that is useful for the calculation of the maximum slope. The range should be right shifted from the injection peaks.

After that, open the calculation window and click the tab Enzyme Kinetic. The following window will appear:

Now you have to choose the input data — that is usually blank corrected raw data or average based on blank corrected data. For the calculation method you can choose between the Michaelis-Menten-Fit, Lineweaver-Burk, Eadie-Hofstee, Scatchard and Hanes-Woolf.

It is very important to type in the unit of the substrate concentrations used. In this case it was µmol per minute. Select the correct range that was defined before in the Signal Curve window. In case that the enzyme was diluted the dilution factor should be announced.

The extinction coefficient can either be typed in (the slope of the standard curve) or can be calculated automatically.

Note: Please note that the automatic calculation of the extinction coefficient is only possible in long-time enzymatic reactions in which the substrate is completely converted into product indicated by no more change in signal.

Consider zero concentration reaction:

Subtract reaction of content with zero concentration: If you run a background reaction at a concentration of zero (but that is not identical to the blank), and you want to subtract this value from all other values, check this control.

Select the content with concentration zero: Select the content that contains the substance with zero concentration from the drop down list (e.g. Positive Control).

Group Handling: If the layout of the test run contains groups, you have to decide how groups are handled:

Use selected content for all groups: Use the selected content of a group for the calculation even if the calculated well is in a different group.

Calculate for each group: Use the selected content of the group of the calculated well. If the group of the well does not have the selected content, no calculation is done for that well.

Ignore groups: Ignore the groups and calculate the result as if no groups were defined.

4.17 Curve Scaling

The Curve Scaling calculation converts a signal curve or a spectrum curve to a percentage presentation between a defined maximum (100%) value of the curve in the selected range and a defined minimum (0%) value. This calculation can be used to normalize the curves:

Input data: Select the input data for the calculation. This can be the raw data or the result of any calculation that obtains kinetic data or spectra data.

If the input data has both, kinetic and spectra data, you can select if the scaling should be calculated based on the kinetic or based on the spectra curve with the radio control above the input data drop down list: Scale kinetic curve / Scale Spectrum curve

Select range: The input data for a curve scaling calculation are always defined by the first cycle/interval and the last cycle/interval of a kinetic range or by the first wavelength and the last wavelength of a spectrum range. It is possible to have one or more ranges defined. The full range is always available and covers the total measurement. See the chapter 4.1: Ranges, how to define a range. All defined ranges are listed in the drop down list with their start and stop cycle/interval or wavelength (depending on the selected input data). Select a range for the calculation from this list. Only ranges with at least three values are shown, because the minimum number of values for the curve analysis is three. To view, create or change a range, press the button to open the range window. You can also define an individual range, where the start and/or stop value is not fix. Select the last entry (Individual Range) in the drop down list to use and define and individual range. Read more about individual ranges in the chapter 4.1: Ranges.

100% Value: Select if the 100% value comes from the maximum of the curve in the selected range or if it is a fix value. Fix values can be entered in the Value entry field. The fix value can also come from a defined variable (see Variables).

0% Value: Select if the 0% value comes from the minimum of the curve in the selected range or if it is a fix value. Fix values can be entered in the Value entry field. The fix value can also come from a defined variable (see Variables).
4.18 Spectrum Calculations

The spectrum calculation page allows you to define a calculation based on a range over a measured spectrum. You can only select it, if the test run is a spectrum scan test.

Input data: Select the input data for the calculation. This can be any process with spectrum data.

**Spectrum range**: The input data for a spectrum calculation are always defined by the first wavelength and the last wavelength of a range. It is possible to have one or more ranges defined over your spectrum. The full range is always available and covers the total measurement. See in the chapter 4.1: *Ranges*, how to define a range. All defined ranges are listed in the drop down list with their start and stop wavelength. Select a range for the calculation from this list. To view, create or change a range, press the **Ranges** button to open the range window. You can also define an individual range, where the start and/or stop wavelength is not fix. Select the last entry (Individual Range) in the drop down list to use and define individual range. Read more about individual ranges in the chapter 4.1: *Ranges*.

**Calculation method**: Select the calculation method for your spectrum calculation.

**Available methods**:

- **Sum**: Calculates the sum of all measurement values for all measured wavelengths within the selected range for each well.
- **Maximum**: Finds the measured maximum value within the selected range for each well.
- **Minimum**: Finds the measured minimum value within the selected range for each well.
- **Local maxima**: Calculates all local maxima within the selected range for each well. See an example of local maxima or minima in the picture below.

For each maximum found, a node in the workflow tree will be created to see the associated value(s) of the maximum for each well (and cycle if it is a kinetic test run). See the section Extended parameters and created result for Local Maxima, Local Minima and Inflection points below for more details. In the same section you can find an explanation of the additional parameters you can use for this calculation method.

**Local minima**: Calculates all local minima within the selected range for each well. See an example of local maxima or minima in the picture below.

For each minimum found, a node in the workflow tree will be created to see the associated value(s) of the minimum for each well (and cycle if it is a kinetic test run). See the section Extended parameters and created result for Local Maxima, Local Minima and Inflection points below for more details. In the same section you can find an explanation of the additional parameters you can use for this calculation method.

**Inflection points**: Calculates all inflection points within the selected range for each well.

For each inflection point found, a node in the workflow tree will be created to see the associated value(s) of the inflection point for each well (and cycle if it is a kinetic test run). See the section Extended parameters and created result for Local Maxima, Local Minima and Inflection points below for more details. In the same section you can find an explanation of the additional parameters you can use for this calculation method.

**Average**: Calculates the average of all measured values within the selected range for each well.

**Slope**: Calculates the linear regression curve for the measured points in the selected range and gives the corresponding slope value for each well.

**Maximum of slope**: Finds the maximum slope value of all measured points within the selected range for each well. The slope is calculated using the entered width: A linear regression fit with the number of measured values entered in the width entry in the *Parameters* group is performed, starting with the first wavelength of the range up to the last. The maximum value of all calculated slopes is the result. You can decide with the *Slope Direction* control in the *Parameters* group whether the rising or the falling maximum value should be calculated.

**Wavelength at threshold**: Calculates the wavelength taken from the first wavelength in the selected range for the curve to reach a given threshold for each well. Enter the threshold value in the entry field *Threshold*, this option appears under the smooth controls when this method is selected. If a spectral curve does not reach the entered threshold, n.a. will be printed as result. You can define, what you want to see instead of n.a. in the result table with the Result, if threshold is not reached drop down menu.

**Output**: Select the desired output values. The available output depends on the selected calculation method. Each selected
output type will be displayed in a separate node or group of nodes in the navigation tree.

Available output types:

**OD value**: This type is available for all calculation methods except Wavelength at threshold. It shows the associated OD Value for the given calculation result.

**Wavelength (nm)**: Not available for the calculation methods Sum, Average and Slope. It shows the associated Wavelength for the given calculation result.

**Slope direction**: Only available for the calculation method Inflection points. The result can have the values -1 for a falling direction, 0 for no slope and 1 for a rising direction.

In addition you can smooth the curve before the calculation to reduce the effect of the noise in the measurement. Check the Smooth curve before calculation control and define the number of moving intervals to smooth the curve.

### 4.18.1 Extended parameters

If one of the calculation methods Local Maxima, Local Minima or Inflection points is selected, in the Parameters group on the left side of the window appears a sensitivity slider control:

Use the Sensitivity slider to define the sensitivity of the calculation. Depending on the spectrum used as input data, a high sensitivity can lead to many (wrong) hits because of the noise of the curve. On the other hand, a very low sensitivity could lead to a bad result as well because of missing real minima, maxima or inflection points.

Consider that the calculation is done for each valid well of the selected input data. This means, that each well has its own minima, maxima and inflection points and the number of calculated results can differ between the wells. The number of created result nodes in the navigation tree will be the highest number of calculated results for all wells in all cycles (if more than one cycle was measured).

Therefore, if you have measured empty or blank wells, they should be excluded from these calculations. Use blank corrected data as input data and toggle out wells with high noise and less information before executing this calculation.

### 4.18.2 Preview the smoothed curves

If you are not sure, how the position of the slider and the entered interval number are affecting the result, you can press the Preview button to open a preview of the result of the calculation:

Use the sliders on the left and right side to see how the result changes. The left slider is only available, if the Smooth curve before calculation control was checked on the calculation window.

Change the displayed well with the Select Well drop down list to see the result for different wells and - if a kinetic with more than two cycles was measured - select the displayed cycle with the Select Cycle drop down list. If the positions of the sliders are optimized and the result is good, press OK to assign the settings to the calculation window.

## 4.19 Statistic over Wells

You can perform a statistic over wells, after selecting two or more wells in the Microplate View. Select the menu item Statistic over selected wells... in the Microplate Views popup menu or in the corresponding menu item under the calculations menu to open this window:

![Statistic over selected wells](image)

Input data: Select the input data for the well statistic. This can be the result of any calculation which outputs the data as numbers.

**Calculation method**: Select the calculation method for your well statistic.

**Available methods**: Average, Standard deviation, Standard deviation n, Standard Error, %CV, %CV n, Minimum, Maximum, Median, Sum, No. of Values.

The available methods are the same as for the replicate and group statistics. For details on the methods, see the chapter 4.5: Statistics.

Press the OK - button on the window to perform the calculation.

### 4.20 Well Scan Statistics

The well scan statistics page is used to calculate statistics over scan points inside a well of a well scan test run.

![Well Scan Statistics](image)

Input data: Select the input data for the well scan statistic. This can be the result of any calculation that obtains well scan data (usually only raw data).

**Calculation method**: Select the calculation method for your well statistic.

**Available methods**: Average, Standard deviation, Standard deviation n, %CV, %CV n, Minimum, Maximum, Median, Sum, No. of scan points.

The available methods are the same as for the replicate and group statistics. For details on the methods, see the chapter 4.5: Statistics.
Press the OK - button on the window to perform the calculation.

If areas where defined inside at least one of the wells (see chapter 3.22: Well Scanning Data, section: Well Scan Area detection) an additional calculation method is available: No. of areas. This returns the number of areas defined in the well.

Furthermore you can decide if the calculation should be performed for the scan points of the entire well or only for the scan points of the defined areas inside a well:

![Calculation options]

**Note:** The well scan statistics average is automatically calculated and displayed, if a well scan test run will be opened the first time.

### 4.21 Standard Calculation Wizard

In most cases it is not necessary to perform each calculation step by step.

Use the standard calculation wizard instead.

The wizard recommends the suitable calculation steps to apply to your standard calculation process.

Click Wizard in the Data Reduction group on the Home tab of the Ribbon. You can find the same control also in the Common group on the Calculations tab. After you've clicked the control, the wizard opens:

![Wizard interface]

#### 4.21.1 When Can You Use the Wizard?

To use the wizard, the test run must fulfill the following conditions:

- The layout must contain one or more standards
- End point test runs may have a maximum of two measured wavelengths
- Kinetic test runs may have a maximum of one measured wavelength (including single wavelength FP-measurements) and not more than one injection.

#### 4.21.2 How the Wizard Works

The wizard recommends calculations depending on the layout and measurement of the test run.

Each available calculation with its parameters is displayed in a separate box on the window.

The user can decide whether he wants to perform the recommended calculations or not by checking or un-checking the check box for each calculation.

The sequence of the calculation is shown from top to bottom and is indicated by the numbers on the left side of the wizard window. This means that the result of a calculation can be used as the input data for the next performed calculation in the sequence.

The parameters of the single calculations are similar to performing the calculation separately by using the calculation window.

### Possible Calculations in the Wizard

#### Blank Correction

- **Blank Correction**
- **Use Blank Corrected Data**

This option will appear if blanks are defined in the layout. When the blank correction is recommended by the wizard, it is checked and always the first calculation step. Uncheck the check box if you do not want to perform a blank correction before creating the standard calculation.

#### Wavelength Calculation

This option will appear only for end point test runs with two measured wavelengths. If you want to plot a standard curve based on a calculation performed on the wavelengths such as the ratio between them, leave the Wavelength Calculation check box checked and select the arithmetic operation you wish to perform from the drop down list between the two wavelengths.

The available calculations are: **minus**, **divide by**, **plus** or **multiplied by**.

If there is a need to swap the wavelengths, select the wavelength in one of the wavelength drop down lists. The entry for the other wavelength is updated automatically.

To multiply the result of a division by a constant value, enter the value into the entry field **Ratio multiplier**.

#### Kinetic Calculation

This group appears only for kinetic test runs. If the test run has an injection, you see two ranges in the group and the injection cycle / interval number. Otherwise you see only one range.

If only one range is visible, the borders of the range are from the first to the last cycle/interval of the measurement.

If there are two ranges, the first range includes the cycles/intervals before the injection, the second range the cycles/intervals after the injection (including the injection).

To change the borders of the ranges use the spin buttons beside the entry fields for the start and stop cycles/intervals or enter numbers into the entry field.
Select the calculation method for the kinetic calculation(s). Read more about kinetic calculation methods in the chapter 4.8: *Kinetic Calculations.*

If there are two ranges, two kinetic calculations will be created, one for each range using the same calculation method.

A kinetic calculation cannot be unchecked, as it is necessary to perform a kinetic calculation before you can perform a standard calculation when you have kinetic test runs.

**Range Calculation**

This option will only appear if the kinetic test run has more than one range selected or has one injection. In this case you have two ranges with two kinetic calculations for the two ranges.

It is possible to perform an arithmetic calculation on the two kinetic calculations (called range calculation in the wizard as the ranges are defining the kinetic calculations).

Select the calculation method using the drop down list between the two ranges.

The available calculations are: **minus**, **divide by**, **plus or multiplied by**.

It is possible to swap the ranges if needed, select a range in one of the range drop down lists. The entry for the other range will be updated automatically.

If you want to multiply the result of a division by a constant value, enter the value into the entry field **Ratio multiplier**.

If you do not want to perform a range calculation, uncheck the check box **Range Calculation**. In this case the standard calculation will be performed for both kinetic calculations.

**Standard Calculation**

The last calculation step is always the standard calculation.

Select the curve fitting method you want to perform using the method drop down list.

If the layout contains dilution factors for at least one sample, the user can decide whether they want to use the dilution factor for the recalculation of the concentration values or not.

Using the two buttons shown for the **X values** and **Y values** the user can decide whether to use a linear or logarithmic scale for each axis.

Read more about standard curve calculation in the chapter 4.10: *Standard Calculations.*

After defining all the parameters of the calculations, press the **OK** button to perform the calculations.

When the calculation of the standard curve has been completed, the page with the standard curve will be displayed in the working area.

If more flexibility is needed to define your calculation than the wizard provides, you can perform the required calculations step by step using the calculations window.

---

### 4.22 ORAC Evaluation

The ORAC assay is used to determine the antioxidant capacity of samples. Often Trolox® (a water-soluble analogue of vitamin E) is used as a standard by which all other antioxidant compounds are compared. There are three templates available that can be used to automatically calculate the Trolox® Equivalents (TE) of the samples.

The ORAC templates can be used if the following criteria are fulfilled:

1. All samples that are not a blank or a control have to be defined as standards using different groups for different substances. The layout can look like this:

   ![Image](image.png)

2. Trolox® or any other reference substance should be defined as standards in group A

3. The concentration of the Trolox® and of the samples should be typed in using the same unit, e.g. µM or mg/l depending on what is known about the sample.

If this layout has not been created before starting the measurement, the layout can be changed afterwards. This is necessary for using the templates. Please read more about changing test run layouts in chapter 6 Change Test Run Layout.

#### 4.22.1 Changing the Layout for ORAC Test Runs

For using the easy ORAC evaluation template, all wells containing samples should be defined as standards in different groups setting the reference substance (Trolox®) into group A. The functions of the Change Test Run Layout window can be used as in the control software for the instrument.

After changing the layout the concentrations of the standard and the samples have to be defined using the other sheet of the window Concentrations/Dilutions/Sample IDs.

The concentration unit of the Trolox® and the samples should be the same, e.g. µM or mg/l. After changing the layout and the concentrations the changes have to be applied by pressing OK.

To save the changed layout permanently, you have to save the test run settings.

After changing the layout one of the ORAC templates can be applied and the calculations of the template will be performed automatically.

#### 4.22.2 ORAC Templates

The ORAC templates available are:

- ORAC no injection
- ORAC 1 injection
- ORAC 2 injections

The assay can be performed either without using integrated pumps or with injection of only the ROS generator (e.g. AAPH – 1 injection) or with injection of the fluorophore (e.g. fluorescein) and the ROS generator (2 injections).
How to use templates is explained in chapter 5: Using Templates.

4.22.3 Optimized Settings for ORAC Measurements

The ORAC templates are created for standard measurement settings and should be adapted if different measurement settings are used (please use the appropriate template depending on the number of injections).

Check in the Signal Curve View if the predefined range is covering the complete time of the measurement. If this is not the case spread the range manually (see chapter 4.1: Ranges).

4.22.4 Trolox Equivalents (TE Values)

After applying the suitable ORAC template and confirming the range, the Trolox® equivalents of the Trolox® standards and all samples are automatically shown in the Microplate View.

The TE values for the reference substance Trolox® should be close to 1.00. The unit of the TE values is either per µmol, mg or ml sample depending on what is known about the sample.

The data node showing the TE result is called Concentration calculations: Ratio calc/known. Next to that the Raw data, Averages or Linear regression fit results can be viewed, too (see chapter 3.3: Microplate View).

4.23 Robust Statistics

Robust statistics provides an alternative approach to standard statistical methods like average, standard deviation and percent coefficient of variation (%CV).

These estimators are not unduly affected by outliers in a sample population. You can also use the Remove Outliers function in MARS to find and remove outliers based on replicates. Sometimes outliers cannot be found easy and sometimes mask each other. Using the robust statistics instead of the standard statistical methods can help to get a better result in such cases.

If the robust statistics is used, equivalents for the mean (average), the standard deviation and the percent coefficient are used:

- Median instead of mean/average.
- robust standard deviation (rSD) instead of SD or SDn: rSD = MAD × 1.4826 where MAD (median absolute deviation) is the median of the absolute value of Xi-Median (i iterates over all replicates of X).
- robust percentage coefficient of variation (%rCV) instead of %CV or %CVn: %rCV = rSD/Medianx × 100%

To activate the robust statistics for an open test run in MARS, select the control Use Robust Statistics in the Common group on the Calculations tab of the ribbon menu.

To activate the robust statistics for all new test runs, select the control Robust Statistics as Default in the Common group on the Calculations tab of the ribbon menu.

If robust statistics is used in MARS, all calculations based on average, SD, SDn, %CV and %CVn are recalculated by using the robust statistics equivalent. A manually performed average calculation is not affected by this control, but you can change this calculation manually into a median calculation.

Affected calculations are such as:

- Z
- Signal to noise
- Signal to blank
- Percentage calculations
- all calculations using an average over replicates like the standard fit calculations.

4.24 Curve Analysis

The curve analysis calculation page provides the two main operations in calculus: Integration and differentiation.

Input data: Select the input data for calculating the curve analysis. This can be the raw data or the result of any calculation that obtains kinetic data or spectra data.

If the input data has both, kinetic and spectra data, you can select if the analysis should be calculated based on the kinetic or based on the spectra curve with the radio control above the input data drop down list: based on kinetic curve / based on Spectrum curve

Select range: The input data for a curve analysis calculation are always defined by the first cycle/interval and the last cycle/interval of a kinetic range or by the first wavelength and the last wavelength of a spectrum range. It is possible to have one or more ranges defined. The full range is always available and covers the total measurement. See the chapter 4.1: Ranges, how to define a range. All defined ranges are listed in the drop down list with their start and stop cycle/interval or wavelength (depending on the selected input data). Select a range for the calculation from this list. Only ranges with at least three values are shown, because the minimum number of values for the curve analysis is three. To view, create or change a range, press the button to open the range window. You can also define an individual range, where the start and/or stop cycle/interval is not fix. Select the last entry (Individual Range) in the drop down list to use and define and individual range. Read more about individual ranges in the chapter 4.1: Ranges.

Calculation method: Select the calculation method for your curve analysis.

Available methods:

Area under curve: Calculates the area under the curve in the selected range using the integration order one. The result is a single value for each curve that represents the area.
**Differentiation**: Calculates the differentiation curve. Select the differentiation order in the entry field below the drop down list. You also can enter a moving interval for the differentiation. If you use a moving interval > 1, not only the dy/dx value of two data points are used to calculate the differentiation in one point, but also the values before and after the data point (moving interval = 5 means: two value pairs before and two value pairs after the current value are used).

**Integration**: Calculates the integration curve. Select the integration order in the entry field below the drop down list.

**Smooth curve for calculation**: To get better results with noisy input data the curves can be smoothed before and after the differentiation/integration. Read more about the possible smooth methods in the chapter 4.7: Curve Smoothing.

### 4.25 Binding Kinetics Calculations

The binding kinetics calculation page is only enabled if it is a kinetic measurement and the layout of the test run contains standards.

**Input data**: Select the input data for the calculation. This can be the result of any calculation that keeps the kinetic data.

**Kinetic range**: The input data for this calculation are always defined by the first cycle/interval and the last cycle/interval of a range. It is possible to have one or more ranges defined over your kinetic. The full range is always available and covers the total measurement. See in the chapter 4.1: Ranges, how to use and define a range. All defined ranges are listed in the drop down list with their start and stop cycle/interval. Select a range for the calculation from this list. To view, create or change a range, press the button to open the range window. You can also define an individual range, where the start and/or stop cycle/interval is not fix. Select the last entry (Individual Range) in the drop down list to use and define individual range. Read more about individual ranges in the chapter 4.1: Ranges.

**Calculation method**: The binding kinetic calculation comes with only one calculation method: Kinetic rate equation. It fits the parameters ka, kd and Rmax of this formula:

\[
R(t; x) = \frac{ka \cdot x \cdot Rmax \cdot (1 - e^{-k(a+kd)x})}{ka \cdot x + kd}
\]

Where x is the signals based on the selected input data and t is the kinetic time value.

With the Time delay field, you can define an offset time for the start of the reaction. The offset is calculated from the first cycle of the measurement.

#### 4.25.1 Calculation Result

After performing an binding kinetics calculation, the result can then be inspected on the binding kinetics fit curve. If this is the first binding kinetics calculation of the test run, the tab for the binding kinetics fit curve page will appear following a successful calculation.

The calculated ka and kd and Rmax values are displayed in the detailed window and can be displayed and exported on the binding kinetics fit result window.

In the microplate and the table view, the value of the fitted signal curve for each standard and for the selected cycle is shown for that calculation node.

#### 4.26 User defined fit formulas

The standard curve fit calculation and the kinetic curve fit calculation offers a user definable fit formula. To use this fit formula, select the last entry (User defined fit) in the fit method pull down list.

After selecting, the window to define the formula opens:

Enter the formula into the Fit Formula entry field and press enter to apply the formula. The formula will be checked for validity and parsed to find the containing parameters. If the formula is valid a table row is created for each fit parameter in the formula. Define the start parameter for each fit parameter and - if desired - a lower and upper limit for the parameter.

A useful start value for the parameters is important for the fit algorithm to find a satisfying result. The closer the start value is to the expected fit result for this parameter, the faster is the fit and the better is the fit result.

To add special operators to the formula, you can click on the operator or functions displayed in the Available operators and functions control or you can enter them directly in the formula edit field.

If you've entered the desired and valid fit formula, click OK to apply the formula to the calculation.

You can change the formula after you've closed this window, if you click on the Edit Formula button on the dialog where the calculation is defined.

#### 4.27 Integration Time Wizard

For data with a measured decay curve (only Alphascreen and TRF measurements) MARS offers a wizard to optimize the integration start and integration time parameters for further measurements.

If a test run with a measured decay curve is opened in MARS, an **Integration Time Wizard** menu in the Data Reduction group on the **Home** tab of the Ribbon appears. After clicking this menu item, the Integration Time Parameter Calculation Wizard opens:
Input data: Select the input data for calculating the integration time matrix. This can be the raw data or the result of any calculation.

Wavelength 1 / Wavelength 2: If the test runs have more than one chromatic, select the two relevant chromatics for the selected calculation. If two different chromatics are selected, the ration of these two chromatics is used for the calculation.

content with lowest/highest concentration: Select the content with the lowest concentration and the content with the highest concentrations.

Calculation: Select the calculation method for your assay quality.

Available methods:

Assay Window: Calculates the ratio between the value of the lowest and highest concentrations content.

$Z^\prime$ (2 prime) factor: Only available, if replicates are defined in the layout. Calculates the $Z$ prime value based on the value of the lowest and highest concentration contents. The formula for the calculation is:

$$Z' = 1 - \frac{(3 \cdot \sigma_1 + 3 \cdot \sigma_2)}{\mu_2}$$

$\mu_1$ is the average of the values over the replicates of the highest concentration content

$\sigma_1$ is the standard deviation over the replicates of the highest concentration content.

$\mu_2$ is the average of the values over the replicates of the lowest concentration content

$\sigma_2$ is the standard deviation over the replicates of the lowest concentration content

$R^2$ of linear fit: Only available, if standards are defined in the layout. Calculates a linear fit based on the standards and uses the resulting $r^2$ value to fill the matrix.

LOD (limit of detection): Only available, if standards and blanks (more than one) are defined in the layout. Calculates a linear fit based on the standards to get the slope for the LOD formula:

$$3 \cdot SD(blank) / Slope$$

$SD(blank)$ is the standard deviation of the blank.

Define the desired input data and calculation and press the Update Table button to calculate the integration matrix. After the matrix is calculated, you can adjust the interval settings for the integration time and integration start range. To reacalculate the matrix with the changed settings, press Update Table again.

Use the color slider on the right side of the table or the color settings button to adjust the color settings for the table.

5 Using Templates

Templates in MARS are a powerful tool to transfer settings, performed calculations and even the result of a standard curve fit to other test runs.

The templates are based on the settings of a test run as they contain all the information needed for the transfer.

In combination with test run protocols, you can get a quick result and report of your performed test without any manual action in MARS needed (see section Why Assign Templates to Protocols? below)

Individual buttons can be created for up to six templates, giving the possibility to change quickly between different views for one test run.

The software comes with a set of predefined templates matching to the predefined protocols for the readers control software. It is possible to use these templates to see how they work.

If you want to use your own templates, you must start by creating a template.

The next step could either be assigning the template to another test run or to a protocol (read more about assigning a template to a protocol in the chapter 5.2: Manage Templates).

If you want to use the template often, you can create a button for that template in the Predefined Templates group on the Home tab and on the Templates tab of the Ribbon and give it a name you like. Details are described in the chapter 5.5: Template Buttons.

If you have a test run with standards and you want to use these standards to calculate the concentration values of samples in a different test run, you can do this using a template. Read how this works in the chapter 5.6: Transfer of Standard Fit Results.

You will soon have a large number of templates. To keep track of your templates, delete or exchange them for others (export / import templates), use the manage templates window.

To parametrize the template, you can use variables. You can decide if the value for the variable will be asked, each time the template is used, or if a manually entered default value is used. Read more about variables in chapter 4.2.1: Define and Use Variables.

Note: Templates are not the tool to transfer modified layouts from one test run to one other. Use the Manage Layout functions to exchange layouts between test runs.

5.1 Why Assign Templates to Protocols?

In many cases the templates will be used more than once and are often applied to test runs, based on the same test run protocol defined with the BMG LABTECH control software for the reader.

If you do not want to assign a new template to each new test run, and equally do not want to add the calculations manually each time you can overcome this by assigning a template to a test protocol.

Assign the template to the test run protocol and for these test runs the template will automatically be assigned to any new performed test run based on that protocol. When the new test run is opened for the first time in MARS the settings defined in the template will be activated.

It is also possible to assign more than one protocol to a template.
To manage the templates and the assigned protocols use the Manage Templates window.

5.2 Manage Templates

To see the existing templates, open the Manage Templates window. This can be done by clicking Templates in the Manage Templates group on the Templates tab of the Ribbon.

The window will open and will show the following functions:

- A list of all defined templates.
- A description of a selected template
- Assigned protocols to the template
- Function to assign and remove protocols from the template
- Function to export and import templates
- Function to delete a template.

5.2.1 List of Templates

The window shows a table with all available templates listed.

The table contains four columns:

- **Table name**: Shows the name of the template.
- **Allowed methods**: The first matching condition: Shows the measurement methods that match the template. The column with the allowed methods can contain a small icon with three dots. This icon appears if the list of matching methods is longer than the column. Click on the icon to see all matching methods:

```
[Images here]
```

- **Type**: The second matching condition: Shows if it is an end point or a kinetic test run template.
- **Assigned Protocols**: Shows the names of the protocols, assigned to the template. This column can also contain the icon with the three dots. Click on it to open a list showing all assigned protocols.

A template can be selected from the list.

The **template description** contains a description of the performed calculations and the settings that will be set if the template is assigned to a test run.

5.2.2 Change Template Name

To change the name of an existing template, select the template and click on **Change Name**... A small window opens to enter the new template name.

5.2.3 Assign Protocols to Templates

After selecting a template, press the **Assign To Protocol(s)** button, to open a window with a list of the protocols and assign one or more protocols to that test run.

At the top of the window you will see the name of the selected template.

The window shows a table with all available protocols in it. The table consists of four columns:

- **Protocol name**: Shows the name of the test run protocol and how it was defined in the control software.
- **Methods**: Shows the measurement method for that protocol.
- **Type**: Shows if it is an end point or a kinetic test run protocol.
- **Template**: Shows the name of an assigned template.

- **LVis**: Shows if the protocol uses a BMG LVis Micro Drop plate or not. This column is only visible, if protocols for the BMG LVis Micro Drop plate are available.

It is possible to select one or more protocol in the list.

After selecting a protocol, you can immediately check if the template can be assigned to that protocol using the **Verify Attributes** table:

This table shows the two matching conditions for the last protocol in the list of selected protocols that must be fulfilled to assign the selected template to that protocol.

The last column of the table shows whether or not the conditions match (yes, allowed or no; allowed with an orange background, no with a red background).

If both criteria are fulfilled for all selected protocols, the **Assign** button is enabled and can be pressed to assign the template to the protocols.

If one of the selected protocols has already been assigned to a template, the link to the old template will be replaced with the new template.

**Enter a protocol name or pattern**

Beside the possibility of selecting a protocol from the list of all available protocols, you can assign a protocol name manually (e.g. if the protocol will be created later), or you can assign a pattern with wild cards. If the protocol name matches the pattern, the template will be assigned to the test run, based on that protocol. Possible wild cards are * (replaces any number of signs) and ? (replacess one sign). This gives you the possibility to assign a template to all test runs created with different protocols, containing the same pattern in their name.
Note: When you assign a protocol name or pattern to the template, MARS cannot check directly, if the protocol and the template will fit together. When the test run will be opened, MARS tries to assign the template if possible. If not, nothing will be assigned.

5.2.4 Removing Assigned Protocols From the Template
Select a template in the list of templates using the ManageTemplates window. If there is at least one protocol in the assigned protocols column, the Remove Protocol(s) button can be used to eliminate the template link from the protocols.

5.2.5 Edit Parameters
If the selected template contains user-defined variables, the Edit Parameters button is enabled. Clicking the button opens a dialog, where the variable in the template can be changed (default values, minimum or maximum values...). An explanation of all different kinds of variables and how to use them in calculations and templates can be found in chapter 4.2.1: Define and Use Variables.

5.2.6 Export and Import Templates
To export templates, select the templates you want to export from the list of templates in the Manage Templates window and press Export....

A file window will open to let you select a file destination for the saved file containing the exported templates (the look and feel of the file window depends on the operating system! The shown window is the file window of Windows Vista.).

Enter a file name for the file and press Save. The generated file gets the extension .mtf. Files with this extension are recognized by MARS as exported templates.

To import templates, they must be exported by MARS (e.g. on another PC) and the file must have the extension .mtf.

Press the Import... button to open a file window similar to the one above. Select the location of the exported file and select the file. Press the Open button in the window to import the template(s) into the list.

5.2.7 Delete Templates
Select one or more templates from the list of templates shown in the manage templates window. To delete the selected templates, press the Delete button.

5.3 Create a Template
A new template can be created from the settings used in an open test run.

This template can then be assigned for use with other test runs that fulfill the two matching conditions:
- The measurement method must be the same
- The read type must be the same. An endpoint template cannot be assigned to kinetic test run and vice versa.

To create a template for use with future test runs you must perform the test once and open it in MARS to create the template.

When creating a template, perform the following initial steps:
- Open the software and select a test run. The test run should be the same type as the test run/s you will assign the template to.
- Perform all the data analysis steps with the test run. When created, the template will then contain all the calculations, selections, view settings etc. of this test run
- Click Create Template from Current Test Run... in the Use Templates group on the Templates tab or select the menu item Create Template from the popup menu in the navigation tree.

On completing the above steps the Create Template window will then open.

Create template window:

Template name
Enter the name of the template you want to create. The name must be unique as it will be used to find the template again. If you want to overwrite an existing template, you can select the template out of the drop down list. To open the list, press the drop down button:

Template description
This section describes the steps performed with the test run and what will be saved in the template. It is possible to expand the entries with your own explanation of the template. The description of the template will be displayed to allow the user to check the suitability of a template before assigning it to other test runs.

Create CSV/Text file / Create PDF report
If needed, a text (CSV) file and/or a PDF report file can be created based on the settings in the template, when the template is assigned to a test run. The settings for the file export or the PDF report can be defined by pressing the according Filename and path settings... button.

Assign Template to Test Protocol
A check box is shown at the bottom of the window along with the name of the test run protocol used to create the template. If you want to assign the new template directly to that protocol, leave the check box checked. If you don’t want to assign the template to that protocol, uncheck the check box.

If you want to assign the template to another protocol, you can do this using the Manage Template window, after creating the template.
Press *Create* to generate the template. If you want to stop the creation of the template, press *Close*.

### 5.4 Assigning Templates

You can assign a template to a test run or to a protocol (see also chapter 5.1: *Why Assigning Templates to Protocols?*).

There are different ways to assign a template to different test runs or protocols:

#### 5.4.1 Assign a Template to a Test Run

When assigning a template to a test run, the template will be used to create the settings for the test run. Templates can be applied to test runs manually if the test run is opened in MARS. The setting for that test run will also be saved automatically after successfully assigning a template to the run. The settings of the test run can still be changed after assigning a template. This is useful when using templates that perform only the first steps of your evaluation.

If a test run is signed (FDA 21 CFR part 11), you cannot assign a template to that test run.

There are four ways in which a template can be assigned to a test run:

- When the test run is opened the first time in MARS and a template is assigned to the protocol of the test run.
- When you select the template, using the Templates control in the Predefined Templates group on the Home or the Templates tab (see Chapter 5.5: *Template Buttons*).
- When you have created a template button for that template and click on the button (see chapter 5.5: *Template Buttons*).
- When you click *Assign Template to Current Test Run*... in the Use Templates group on the Templates tab or the menu item *Assign Template* of the pop up menu in the navigation tree and choose the template in the appearing assign template window.

**Assign Template Window**

![Assign Template Window](Image)

On the top of the window the name of the current test run to which the template will be assigned is displayed.

**Template list and template description**

Click on a template in the table to view the description of the template in the template description area under the table.

The table has three columns:

- **Table name**: Shows the name of the template.
- **Allowed methods**: The first of the two matching conditions: Shows the measurement methods that match the template. This column shows the allowed methods and can contain a small icon with three dots. This icon appears if the list of matching methods is longer than the column. Click on the icon to see all matching methods:

![Template Matching Conditions](Image)

- **Type**: The second matching condition: Shows if it is an end point or a kinetic test run template.

**Verify Attributes**

This table shows the two matching conditions for the test run and the selected template that must be fulfilled to assign the template to that test run.

The last column of the table shows if the test run conditions match to the template:

- **yes**: the combination is possible
- **allowed** (with an orange background color): the combination is possible but with restrictions.
- **no** (with a red background): the combination is not allowed.

If both criteria are fulfilled or at least allowed, the *Assign* button is enabled and can be pressed to assign the template to the test run.

**Note**: If the template contains kinetic settings but the test run don’t have kinetic data, the combination is allowed, but the kinetic settings will not be applied to the test run.

**Assign template to test protocol**

A check box is shown at the bottom of the window along with the name of the test run protocol used to create the template. If you want to assign the new template directly to that protocol, leave the check box checked. If you don’t want to assign the template to that protocol, uncheck the box.

**Templates with variables**

A template can contain variables. You can see if a template contains variables in the template description. Containing variables are shown with their variable name (like V1, V2...) and a description.

The variables in the template will be replaced by certain values if you assign the template to the test run. Depending on the kind of variable, the value will be asked to be entered or the defined default value is used.

Read more about variables in chapter 4.2.1: *Define and Use Variables*.

#### 5.4.2 Assign a Template to a Protocol

There are three ways to assign a template to a protocol:

- When creating a template (see chapter 5.3: *Create a Template*).
- When assigning a template to a test run using the assign window (see Assign Template Window above).
- In the Manage Template window.
Read more about templates with protocols in the chapter 5: Using Templates.

5.5 Template Buttons

The Predefined Templates group on the Home tab and on the Templates tab comes with two default buttons for templates:

This button gives quick access to all available templates for the current test run. See the section Templates Button below.

This button creates a new template button in the Predefined Templates group. The template buttons created provide quick and easy access to the templates most frequently used. See the section Add a User Template Button below.

5.5.1 Templates Button

The Templates control in the Predefined Templates group on the Home tab and on the Templates tab shows a list of all templates available for use with the current test run. To open the list click on the button or on the small down arrow on the right side of the button:

Click on a template in the list to assign that template to the current test run.

If no template is available for the current test run or if the current test run is signed the button is disabled.

5.5.2 Add a User Template Button

You can have up to six user template buttons in the Predefined Templates group. Each button has the same icon in a different color and an explaining text under the button:

The user button is enabled if the underlying template is assignable to the current test run. Otherwise the button is disabled. Pressing the button will assign the template to the current test run.

If there are less than six template-buttons (if you start the software first and you have never added a user button before, there will be no template buttons visible), a new button can be created by clicking Add Button in the Predefined Templates group:

New Template Button Window

At the top of the window a table is shown with all available templates. The table consists of three columns:

Table name: Shows the name of the template.

Allowed methods: The first of the two matching conditions: Shows the measurement methods that match the template. This column shows the allowed methods and can contain a small icon with three dots. This icon appears if the list of matching methods is longer than the column. Click on the icon to see all matching methods:

Type: The second matching condition: Shows if it is an end point or a kinetic test run template.

The template description shows the steps, the template will perform on the test run if you assign it.

At the bottom of the window you can enter a name for the button in the entry field Button Name. The entered name will appear under the button in the Predefined Templates group.

Select the template to be linked to the button in the table.

Click the Create button to add this button representing the selected template to the Predefined Templates group.

The new button will appear between the last user button created and the Add Button in the Predefined Templates group.

5.5.3 Changing and Deleting User Template Buttons

Templates associated with a user template buttons can be changed and user template buttons can be deleted.

Press the small down arrow on the right side of the button to see the two menu items with the mentioned functions.

Select Delete Template Button to delete the button.

Select Change Assigned Template... to open the window for changing the user button:
The window is the same as if a new template button is created (see New Template Button Window above). Additionally it shows the name of the assigned template at the top of the window. The assigned template is also selected in the template table.

The associated template and the name of the user template button can be changed.

Press Assign to accept the changes.

Note: If the user template button is disabled, changing or deleting the button as described in this chapter is not available. Use the Manage Template Button window instead.

5.5.4 Manage Template Buttons

You also can add, change and delete user template buttons with the Manage Template Buttons window:

Use this window to change or delete a template button if it is disabled.

5.6 Transfer of Standard Fit Results

If a test run is created without standards in the layout, it is possible to apply the standard curve fit of another test run to these samples to calculate the sample concentrations in the sample test run. Both the sample test run and the standards test run must be the same type to enable the transfer of the standard fit from the standards test run to the sample test runs:

- Run the measurement(s) for the test run(s) without the standards.
- Open the measured test run with MARS.

If the template was assigned to the protocol, the calculation will start automatically when the test run is opened. Otherwise the template with the standard calculation can be assigned after the test run has been opened.

Blanks will also be transferred to the test run, if the test run with the standards had blanks and in the layout of the test run are no blanks defined.

The calculation of the concentration values for each well used in the test run will then be done and the result can be viewed in the microplate or table view.

If the template contains more than one standard calculation, each of the calculations will be performed.

The standard curve of the fit used can also be inspected in the standard curve chart. The standards in the chart are shown in gray to indicate that they are not part of this test run.

The transferred standard calculation parameter cannot be changed anymore and single standards cannot be set to unused.

The regimentation for transferring standard calculations to test runs with no standards are very small. Only the two conditions to assign a template to a test run must be fulfilled:

- The measurement method must fit
- Both test runs must be either end point or kinetic test runs.

Note: To get a valid result you must ensure, that the measurement conditions are comparable. All parameters that have a direct influence to the measurement signal must be identical. See the table with parameters you have to check below.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Measurement Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>used gain</td>
<td>all</td>
</tr>
<tr>
<td>used filter / top or bottom optic</td>
<td>all</td>
</tr>
<tr>
<td>/ used optic type / used optic module / used wavelength (absorbance spectrum)</td>
<td>all</td>
</tr>
<tr>
<td>used microplate (No. wells, plate type, plate color)</td>
<td>all</td>
</tr>
<tr>
<td>used volumes</td>
<td>all</td>
</tr>
<tr>
<td>No. of used flashes</td>
<td>TRF / HTRF</td>
</tr>
<tr>
<td>integration start time and integration time</td>
<td>TRF / HTRF, Alphascreen</td>
</tr>
<tr>
<td>excitation time</td>
<td>Alphascreen</td>
</tr>
<tr>
<td>measurement time</td>
<td>Luminescence</td>
</tr>
<tr>
<td>temperature</td>
<td>all</td>
</tr>
<tr>
<td>focal height (if adjustable - depends on the reader)</td>
<td>all</td>
</tr>
<tr>
<td>path length correction</td>
<td>Absorbance</td>
</tr>
</tbody>
</table>

Note: If you use a template with a standard calculation for a test run that contains standards, the standard calculation is performed based on the standards in that test run.

6 Test Run Layout

6.1 Changing Layout

The layout of a measured test run can be changed subsequently with MARS. You can change each parameter of the layout for the measured wells in the microplate: The layout content, the layout group, concentration / dilution values, sample IDs and the concentration unit. You also can change the plate IDs (1-3) of the test run.
Note: Changing the layout of a test run may affect already calculated results or even delete a result that cannot be calculated any more.

The original layout of the test run (the layout of the measured protocol) is kept and the changed layout can be reset to the original layout at any time. Deleted results will not be restored after resetting the layout!

To change the layout of a loaded test run, click Change Test run Layout in the Test Run Layout group on the Layout tab or press the button in the layout view window. You also can click on the change layout icon on top of the Microplate View. A window with the actual layout opens:

![Layout View Window]

How to change the single parameters of the layout is described in the next sections of this chapter.

After finishing the changing of the layout, press the OK button to apply the changes to the test run. A hint window will be displayed that describes the consequences for the actual performed calculations. Confirm this dialog to apply the changes.

After applying the changes, the settings of the test run with the changed layout will be saved automatically. With the button you can open a stored layout to use it for this test run. Only saved layouts that match to the test run are provided. The condition when a layout matches to a test run is described in Manage Layouts.

To save the layout of the test run and use it with other test runs, press the button.

Read more about saved layouts in Manage Layouts.

Press the button to undo the last changes.

### 6.1.1 Changing Plate IDs

To change the plate IDs of the test run, enter the new values into the Plate ID fields ID 1, ID 2 and ID 3.

**Note:** The plate IDs of a test run are used to identify a test run. Consider not to overwrite auto generated IDs if these IDs are used as a unique identification of the test run!

### 6.1.2 Changing Layout Contents

Changing the contents of a well works the same way as defining well contents for protocols in the control software. Select the content type first by clicking the appropriate content button (Sample, Blank, Standard...) and then use ways to select wells as described below.

<table>
<thead>
<tr>
<th>ID</th>
<th>Content Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>X</td>
<td>Sample: The well’s content has unknown concentration.</td>
</tr>
<tr>
<td>B</td>
<td>Blank: The well contains water or buffer for measuring</td>
</tr>
<tr>
<td></td>
<td>background.</td>
</tr>
<tr>
<td>S</td>
<td>Standard: The well’s content has a known concentration</td>
</tr>
<tr>
<td></td>
<td>and can be used to formulate a standard curve.</td>
</tr>
<tr>
<td>N</td>
<td>Negative Control, Positive Control, Control: The well’s</td>
</tr>
<tr>
<td></td>
<td>content has known concentrations, but will not be</td>
</tr>
<tr>
<td></td>
<td>used for the standard curve calculation. It can be</td>
</tr>
<tr>
<td></td>
<td>used for comparisons or for special calculations.</td>
</tr>
</tbody>
</table>

The first letter in the cell of a well indicates the content type (when fewer than 384 wells are displayed. Otherwise only the color of the label indicates the content):

The Index is the reference number of the sample or the standard. The index box displays the number that will be used for the next well. If increase is selected, each well will be labeled successively. Constant will keep the same number in the case of continuous replicates.

If fewer than 384 wells are displayed, the index is the number behind the content letter. Otherwise only the index is displayed in the cell.

Replicates are the number of repeated samples or standards in a row. If you have duplicates on the microplate, you can select the number of replicates and whether they are labeled in the horizontal or vertical direction on the microplate.

If you want to use layout Groups (in MARS you can use up to 125 layout groups unlike in the control software where the limit is 26 layout groups), activate the usage of groups with checking the On check box and select the desired group in the drop down list. The group will be shown in the layout grid using different background colors and by inserting the group letter at the end of the label for the well (if fewer than 384 wells are displayed. Otherwise only the background gets the according color of the group). In general, groups are represented by a group letter, starting with A for the first group and ending with DU for group number 125. To individualize the representation of the groups, you can enter Group IDs for each group. Press the button to open the window, where the group IDs can be entered and changed:

**Methods of selecting wells to fill out the labels:**

There are several ways to label the plate, after content, index and replicate settings are defined:

1. Double click on each well of that type.
2. If the wells of that content are in successive rows or columns, click on the first well with the left mouse key and drag across the wells containing the same content.
3. If a total row or column contains the same content, click the row letter or the column number and all wells of that row / column will be labeled.
4. To fill the entire microplate click on the format number (e.g. ’96’) in the top left corner.
Note: Unmeasured wells are disabled in the grid as you cannot define content for unmeasured wells!

6.1.3 Changing Concentrations, Dilutions and Sample IDs
To change the known concentrations of standards or controls and the used concentration unit, the dilution factor of samples or controls or the sample IDs of the contents, go to the Concentrations / Dilutions / Sample IDs sheet.

The sheet contains a table with all wells of the layout. You can enter the new concentration or dilution values and the sample ID.

For the concentrations and dilution values you can use the auto fill out function that works the same way as entering these values in the test definition of protocols in the control software.

The table can be sorted, grouped and filtered by the columns Well Row, Well Col, Content and Group (the group column appears only if layout groups are used). More information is given about sorting, grouping and filtering in tables in the chapter 2.2: Group and Filter Test Runs, as it works the same way as for test runs.

Concentration values can only be entered for wells with content type standard, control, positive control and negative control. The dilution values can only be entered for all wells but not for blanks and standards.

The auto fill out function can be used to define the concentrations and dilutions without entering them manually. The values will automatically be calculated using the given Start value and a number multiplied with (Factor), added to (Increment) or subtracted by (Decrement) the last calculated value.

Click with the left mouse button on the header of the according column to fill out all wells. You can also select a specific set of successive wells by selecting them with the left mouse button down.

Enter the unit for the concentration values in Concentration unit.

If you enter concentration values, dilution values or sample IDs and the layout contains replicates, the entered values or IDs will be assigned to all replicates automatically. To enter different dilution values or sample IDs for each replicated well the options Allow different dilution factors for replicates and Allow different sample IDs for replicates must be activated. To activate these options, open the MARS Settings dialog (chapter 3.24.1) and check the appropriate check box controls.

You can use the windows copy and paste function to exchange data (concentrations, dilutions and/or sample ids) between MARS and other programs like Excel. To copy data in the list, select them with the mouse and press the keys Ctrl+C or open the popup menu with the right mouse button and select Copy. To import data in the windows clipboard, select the first cell in the table, where the import should start and press the keys Ctrl+V or open the popup menu with the right mouse button and select Paste.

6.1.4 Changing Path Length Correction Settings
If the measurement method of the test run is absorbance or absorbance spectrum, you can change the settings for the path length correction. To see and change the settings go to the Path Length Correction sheet.

Note: This sheet is only available for test runs created with the reader families OMEGA, PHERAstar version 2.10 and higher, SPECTROstar Nano version 2.00 and higher or CLARIOstar version 5.00 and higher.

To activate the path length correction, check the according check box control. Enter the used volume in the wells in the entry field Volume. The resulting path length is shown in mm. The absorbance values will be recalculated as values measured with a path length of 10mm.

To go back to the values defined when the test run was created/measured, click the Use protocol settings button.

Note: Test runs measured with the BMG LVis Micro Drop plate do not have a volume field to enter. The path length of the BMG LVis Micro Drop is known and independent of the used volume. For these test runs you only need to switch the correction on or off.

6.1.5 Changing Crosstalk Correction Settings
If the measurement method of the test run is luminescence or AlphaScreen, you can change the settings for the crosstalk correction. To see and change the settings go to the Crosstalk Correction sheet.

Note: This sheet is only available for test runs created with the reader families PHERAstar or CLARIOstar.

To activate the crosstalk correction, check the according check box control. Enter the used glow correction factor for luminescence measurements. For AlphaScreen test runs you need to define the afterglow correction factor and the glow correction factor. For dual channel or multichromatic test runs, a factor for each channel and chromatic must be defined. The correction can lead to negative values. To prevent negative values, check the 'Set negative values to zero' control. The raw data values will be recalculated using the entered correction factor.

To go back to the values defined when the test run was created/measured, click the Use determined factor button.

6.2 Manage Layouts
The Manage Layouts function provides you the possibility to create new layouts or layouts out of a test run, to change the layouts and to exchange the layouts using the export and import functionality. These layouts can be assigned to a test run, if the saved layout fits to the test run.
Click **Layouts** in the **Manage** group on the **Layout** tab to open the manage layout window:

The window contains a list with all saved layouts, containing the name of the layout and the size of the microplate. The dialog above shows the layout of a 96 well microplate. After selecting one layout in the list, the grid on the right side of the list shows the used wells in the save layout. The plate size and the used wells are important information as the decision if a saved layout can be assigned to a test run is based on this information.

### 6.2.1 Assign a Saved Layout to a Test Run

You can assign saved layouts to test runs. Therefore the two conditions must be fulfilled:

1. The size of the microplate of the test run and the saved layout must be identical.
2. The used wells in the saved layouts must be measured wells in the test run (there can be more measured wells in the test run but not in the saved layout).

There are four ways to assign a saved layout to a test run:

1. With the manage test run dialog above: Open the test run and then the manage layouts window. Select one layout in the list. If the layout can be assigned to the test run, the **Assign to test run** button is enabled and must be pressed to assign the layout.
2. With the menu item **Assign Layout to Test Run**: Open the test run and select the menu item. A window similar to the **Manage Layout** window shown above, appears.

The list with the saved layouts contains only the assignable layouts. Select a layout and press **OK** to assign the layout to the test run.

3. With the change test run layout window: Press the **Load Layout** button on the window. You see the same window as shown above. Select the desired layout and press **OK**. The layout will be displayed in the **Change Layout** window and overwrite the layout displayed before. Press **OK** on the **Change Layout** dialog to apply the new layout.
4. With the **Manage Test Run** window: Select one or more test runs of the same microplate size and open the popup menu by clicking the right mouse button. Select the menu item **Assign Layout**. Select the layout and press **OK**. The layout will be assigned to each selected test run if possible (see conditions above). If the layout cannot be assigned to one or more test runs, a message with a list containing the not assignable test runs appears.

If a test run is opened, you get a hint how the changed layout will affect your calculated results.

**Note:** Plate IDs are not part of the saved layouts and will not be changed after assigning a saved layout to a test run.

### 6.2.2 Create and Edit Saved Layouts

Press the **New Layout** button to create a new layout. After selecting the size of the microplate the new layout can be entered as described in. Press the **Save** button to save the new layout. You will be asked to enter a name for the new layout.

To view and change a saved layout, select the layout and press the **Edit Layout** button. Change the layout as described in chapter 6.1: **Changing Layout and press **Save** to apply the changes.

### 6.2.3 Delete Layouts

Select one or more layouts in the list and press the **Delete Layout(s)** to delete the saved layouts.

### 6.2.4 Export and Import Layouts

You can export the saved layouts and exchange them with others. Select the layouts you want to export and press the **Export Layout(s)** button. Select a directory to save the layouts. You can change the recommended filename. The file extension of the exported layout files is MLF.

To import layouts in a MLF file, press the **Import Layout(s)** button and select the directory with the MLF file. Select the file and press the **Import** button.

### 7 Sign a Test Run

To ensure that your measured result and your performed evaluation on the test run cannot be changed or manipulated you can sign the test run.

The ability to sign a test run is also needed to fulfill the FDA 21 part 11 compliance. Read more about this in the software manual part IV: FDA 21 CFR part 11.

To sign a test run, you need a pair of RSA keys. How to get such keys is also described in the software manual part IV: FDA 21 CFR part 11.

Click **/\** in the **Test Runs** group on the **Home** tab of the ribbon to sign the opened and selected test run. The authentication window will then appear:
After logging in, it is possible to enter a comment to the signature:

![Signature window](signature_window.png)

Press OK to finish the sign process.

Signed test runs are indicated with a blue sign text in the test run description area on top of the working area.

An entry in the audit trail is generated and you can see the signature on the 21 CFR part 11 pages.

It is possible to add more than one signature to a test run (e.g. one for released and one for reviewed...)

If a test run is signed, you cannot save any more changes made in the software for that test run. You can make a copy of the test run and change the copied test run because the signature will not be copied.

8 Support

If you have any problem / question regarding the software / the instruments, you should visit the support section on our web page (http://www.bmglabtech.com) or contact BMG LABTECH using the following email addresses:

- Problems / questions regarding software: support@bmglabtech.com
- Problems / questions regarding the instruments: techsupport@bmglabtech.com

You can also use our technical request form (http://www.bmglabtech.com/support/countryselect.cfm).

Note: When you need support from BMG due to a software / firmware malfunction, you should send us the run log file together with the error description.
